## EXECUTIVE SUMMARY

In 1974, the United States Atomic Energy Commission (USAEC), a predecessor to the U.S. Department of Energy (USDOE), instituted the Formerly Utilized Sites Remedial Action Program (FUSRAP). This program is now managed by United States Army Corps of Engineers (USACE) to identify and clean up, or otherwise control, sites where residual radioactivity remains from the early years of the nation's atomic energy program or from commercial operations causing conditions that Congress has authorized USACE to remedy under FUSRAP. In October 1997, Congress transferred the responsibility for FUSRAP from the USDOE to the USACE.

This memorandum presents results obtained as part of the 2006 environmental surveillance program for the Niagara Falls Storage Site (NFSS) under the FUSRAP. Because radioactive wastes and residues are stored in the interim waste containment structure (IWCS) at the NFSS, the environmental surveillance program at the site includes sampling of air, water, and streambed sediment to ensure that onsite waste does not pose a threat to human health and the environment. The discussion below provides a comparative analysis of local background conditions and regulatory criteria to results reported for external gamma radiation and for samples from the media investigated. Data tables and figures referenced in the text are included at the end of this document.

The USDOE and United States Environmental Protection Agency (USEPA) guidelines are cited throughout this report to aid in the evaluation of environmental data. This memorandum compares data with USDOE guidelines because the USDOE has "property accountability" for the site. The guideline values do not represent cleanup criteria. Cleanup criteria will be developed in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) process. The preferred remedy will be presented in the Proposed Plan, which the public will be able to comment on, and final Applicable or Relevant and Appropriate Requirements (ARARs) will be determined during the Proposed Plan and presented in the Record of Decision (ROD). Results from the 2006 surveillance program at NFSS indicate that no measured parameter exceeded USDOE guidelines and no dose calculated for potentially exposed members of the general public exceeded USDOE or USEPA limits.

Prior to transfer of the FUSRAP to USACE in 1997, reports were generated based on USDOE Orders and guidance. USDOE Orders are not applicable to the activities of the USACE as the USACE is not under the authority or direction of the USDOE. However, the surveillance data continues to follow a format similar to that of the previous USDOE reports to provide the reader with consistent presentation of data and to facilitate historical comparison between reports.

### 1.0 INTRODUCTION

The Niagara Falls Storage Site (NFSS) is located in the Town of Lewiston in northwestern New York State, northeast of Niagara Falls and south of Lake Ontario (Figure 1, Appendix A). NFSS is approximately 77 hectare ( 191 acre) site which includes: one former process building (Building 401), one office building (Building 429), an equipment shed, and a 4 hectare ( 9.9 acre) interim waste containment structure (IWCS). The property is fenced, and public access is restricted.

Land use in the region is primarily rural residential; however, the site is bordered by a state and federally regulated chemical waste disposal facility to the north, a solid waste disposal facility to the east and south, and a National Grid Power Corporation right-of-way to the west. The nearest residential areas are approximately $1-\mathrm{km}$ southwest of the site; the residences are primarily single-family dwellings.

Beginning in 1944, the NFSS was used as a storage facility for radioactive residues and wastes. The residues and wastes are the process by-products of uranium extraction from pitchblende (uranium ore). The residues originated at other sites and were transferred to the NFSS for storage in buildings, onsite pits, and surface piles.

Since 1971, activities at NFSS have been confined to residue and waste storage and remediation. Onsite and offsite areas with residual radioactivity exceeding USDOE guidelines, were remediated by the USDOE between 1955 and 1992; materials generated during remedial actions (approximately $195,000 \mathrm{~m}^{3}$ ) are encapsulated in the IWCS, which is specifically designed to provide interim storage of the material.

### 1.1 Measured Parameters

The key elements of the 2006 environmental surveillance program at NFSS were:

- measurement of external gamma radiation;
- measurement of radon gas concentrations in air (combined contributions from radon-220 and radon-222);
- monitoring of radon-222 flux (rate of radon-222 emission from the IWCS);
- sampling and analysis of surface water for isotopic uranium (U-234, U-235, U-238) \& total uranium (sum of these three isotopes), isotopic thorium (Th-230, Th-232) and isotopic radium (Ra-226, Ra-228) (referred to collectively as radioactive constituents);
- sampling and analysis of streambed sediments for radioactive constituents; and
- sampling and analysis of groundwater for radioactive constituents, metals, and water quality parameters.

### 1.2 Unit Conversions

The tables in Appendix A (Table A.1\& A.2, Page T-1) list the units of measurement and appropriate abbreviations used in this document. Conventional units for radioactivity are used because the regulatory guidelines are generally provided in these terms.

### 2.0 REGULATORY GUIDELINES

The primary regulatory guidelines that affect activities at Formerly Utilized Sites Remedial Action Program (FUSRAP) sites are found in Federal statutes and in Federal, State, and Local regulations. Regulatory criteria that were used to evaluate the results of the 2006 environmental surveillance program at NFSS are summarized below, categorized by media and parameters. In several cases USDOE guidelines continue to be identified in the technical memorandum for comparison purposes of historical data collected by USDOE or their contractors. USACE is not under the authority of the USDOE orders or directives and must rely on other applicable Federal or State regulations in relation to surveillance of the IWCS. The values are for comparison only.

### 2.1 External Gamma Radiation and Air (Radon Gas and Airborne Particulate)

The regulatory guideline criteria used in evaluation of the calculated maximum doses from external gamma radiation and inhalation of radioactive particulate and the measured concentrations of radon gas include USDOE guidelines, United States Environmental Protection Agency (USEPA) standards, and USEPA guidance.

### 2.1.1 USDOE Order 5400.5

Dose limits for members of the public from USDOE operations at USDOE-owned and USDOE-operated facilities are presented in this USDOE Order. The primary dose limit is expressed as an effective dose equivalent. The limit of $100-\mathrm{mrem}$ effective dose equivalent above background in a year from all sources (excluding radon) is specified in this Order; external gamma radiation dose and the calculated doses from airborne particulate releases are included in the calculation of the effective dose equivalent total. Also, this calculation includes contributions from other pathways, such as ingestion.

USDOE limits for radon concentrations in air from USDOE operations at USDOE-owned and USDOE-operated facilities are also presented in Order 5400.5. Based on the radioactive constituents in the wastes contained in the IWCS, it is unlikely that radon-220 would be emitted from the IWCS since the radon- 220 half-life is approximately 55.6 seconds and this isotope would decay prior to permeating through the IWCS cap. It is, however, possible that radon- 222 with a half-life of 3.8 days could be emitted. The USDOE limits for radon-222 concentrations in the atmosphere above facility surfaces or openings in addition to background levels are: $100 \mathrm{pCi} / \mathrm{L}$ at any given point; an annual average concentration of $30 \mathrm{pCi} / \mathrm{L}$ over the facility site; and an annual average concentration of $3.0 \mathrm{pCi} / \mathrm{L}$ at or above any location outside the facility site. To provide a conservative basis for comparison, on-site radon concentrations are evaluated against the off-site limit of $3.0 \mathrm{pCi} / \mathrm{L}$ above background.

### 2.1.2 USEPA Standards and USEPA Guidance

## Radon

The USEPA also has a guidance action level of $4.0 \mathrm{pCi} / \mathrm{L}$ for radon concentrations for indoor air (homes and buildings), providing another conservative basis for comparison. Although these limits are specific to indoor air, they provide a conservative basis for comparison to the outdoor air results obtained during environmental surveillance activities, for details see Appendix C. For further comparison, the average radon level in US homes is about $1.25 \mathrm{pCi} / \mathrm{L}$ and the average outdoor value is $0.4 \mathrm{pCi} / \mathrm{L}$ (USEPA 1993).

## Clean Air Act

Section 112 of the Clean Air Act authorized the USEPA to promulgate the National Emission Standards for Hazardous Air Pollutants (NESHAPs) which are given in 40 CFR 61. Compliance with Subpart H (for non-radon, radioactive constituents) is verified by applying the USEPA-approved CAP88-PC model. Compliance with Subpart Q is verified by annual monitoring of the IWCS for radon-222 flux (See Appendix A, Table B, Page T-1).

### 2.2 Sediment, Surface Water, and Groundwater - Radioactive Constituents

Regulatory criteria for evaluating the measured concentrations of radionuclides in sediment, surface water, and groundwater at NFSS are as follows.

### 2.2.1 USDOE Order 5400.5

This Order provides guideline limits for radioactive contaminants in water and soil at US DOE-owned and US DOE-operated facilities. US DOE historically applied the residual soil cleanup guideline criteria specified in USDOE Order 5400.5 to sediments. However, those values are provided for comparative purposes only. ARARs and specific cleanup goals will be evaluated independently and presented in the proposed plan for public comment. The standards and cleanup goals will be documented in the record of decision (ROD).

Section 5.5 presents the data for this years technical memorandum and describes the basis for comparisons with US DOE Order 5400.5 limits in detail.

### 2.2.2 Safe Drinking Water Act (SDWA)

Shallow groundwater resources at NFSS demonstrate uniformly poor groundwater quality and availability in the general region. Regional studies and studies conducted near the site
(La Sala 1968; Wehran 1977; Acres American 1981) conclude that groundwater quality is poor near the site because of high mineralization (see section 5.6.2.2 Water Quality Parameters). Additionally, local studies (Wehran 1977 and Acres American 1981) indicate that the permeabilities of the shallow groundwater systems are sufficiently low that it is not practicable to obtain groundwater from these systems for water supply. Onsite permeability testing at NFSS confirms the low permeabilities.

The USDOE conducted a well survey in 1988 and inventoried eight wells within 4.8 km of the site, none of which were reported as drinking water but mainly irrigation (USDOE 1994b). In 2006, the Niagara County Department of Health (DOH) updated its well inventory to include 9 potable wells (two of which were sole source), 8 non-potable wells, 20 abandoned wells and 77 idle wells within the survey area. Based on the USDOE report and recent DOH survey the NYSDEC Class GA groundwater standards represent a conservative basis for comparing analytical results. Groundwater at NFSS consistently exceeds sodium and sulfate Class GA standards. Both the shallow and deep groundwater units at the NFSS exhibit over $1000 \mathrm{mg} / \mathrm{L}$ Total Dissolved Solids (TDS) and the deep groundwater commonly over $100 \mathrm{mg} / \mathrm{L}$ Chloride, which indicates that the site groundwater can be classified as saline or Class GSA (NYCRR 701.16). However, to establish a basis for comparison of analytical results, Class GA (groundwater) water quality standards for some constituents were obtained from the NYSDEC document.

SDWA is the primary Federal law applicable to the operation of a public water system and the development of drinking water quality standards [USEPA Drinking Water Regulations and Health Advisories (USEPA 1996)]. The regulations in 40 CFR Part 141 (National Primary Drinking Water Regulations) set maximum permissible levels of organic, inorganic, radionuclides (including uranium and combined radium) and microbial contaminants in drinking water by specifying the maximum contaminant level (MCL) for each. The established (promulgated) MCL for combined concentrations of radium-226 and radium- 228 is $5 \mathrm{pCi} / \mathrm{L}$. The USEPA National Primary Drinking Water Regulation for Radionuclides (Final Rule - effective 2003) states a MCL of $30 \mu \mathrm{~g} / \mathrm{L}$ for total uranium. Although groundwater at NFSS is not a public drinking water supply, MCLs for drinking water are used as a conservative basis for evaluation of analytical results, maintaining consistency with previous reports and facilitating trend analysis (See Table C in Appendix A, TABLES section, page T-2).

### 2.3 Groundwater - Chemical Parameters

Although groundwater at NFSS is not a public drinking water supply, State and Federal standards (Table D, Appendix A) are used as a basis for evaluation of chemical analytical results.

### 2.3.1 Safe Drinking Water Act

As indicated previously, SDWA is the primary Federal law applicable to the operation of a public water system and the development of drinking water quality standards (USEPA 1996). The regulations set MCLs for organic, inorganic, radiological and microbial contaminants in drinking water. In some cases, secondary maximum contaminant levels (SMCLs), which are not federally enforceable (40 CFR 143.1), are provided as guidelines for the states. SMCLs are provided for a conservative comparison of analytical results and to provide consistency with previous reports and facilitate trend analysis.

### 2.3.2 New York State Department of Environmental Conservation (NYSDEC) Water Quality Criteria for Groundwater

NYSDEC has adopted the Federal SDWA standards into its own regulations in Title 6 New York Codes of Rules and Regulations (NYCRR) Parts 700-705, "Water Quality Regulations for Surface and Groundwater" (NYSDEC 1996). In addition, NYSDEC has independently established standards for some constituents. To apply established standards, the State of New York categorizes groundwater resources by groundwater quality and use.

The Division of Water Technical and Operational Guidance Series (TOGS) specifically address source drinking water standards (NYSDEC - 6 NYCRR Part 703 Surface Water and Groundwater Quality Standards and Groundwater Effluent Limitations (August 1999)). These standards have been used to establish additional Class GA (related, conservative case) state water quality standards for comparison of analytical results.

### 3.0 SAMPLING LOCATIONS AND RATIONALE

Radioactive materials that exceed USDOE cleanup guidelines at NFSS are stored in the IWCS. Exposure of members of the public to this radioactively contaminated material at NFSS is unlikely because of site access restrictions (e.g., fences) and engineering controls (e.g., pile covers). However, potential pathways include direct exposure to external gamma radiation and inhalation of air containing radon or radioactively contaminated particulates from site soils; and contact with, or ingestion of, contaminated surface water, streambed sediments, or groundwater. The environmental surveillance program at NFSS has been developed to provide surveillance of these exposure routes through periodic sampling and analysis for radioactive and chemical constituents. Figure 2 (Appendix A, page F-2) presents sampling locations and media associated with the environmental surveillance program at NFSS. A summarization of the environmental surveillance program at NFSS for external gamma radiation, radon gas, surface water, sediment, and groundwater can be found in Appendix A, Table 1, page T-1.

External gamma radiation monitoring and radon gas measurements occur at fence line locations surrounding the NFSS as well as interior portions of the site, including the perimeter of the IWCS, to assess potential exposures to the public and site workers. Measurement of radon-222 flux is conducted annually at discrete grid intersections on the IWCS (Appendix A, Figure 2, page F-2).

Groundwater monitoring wells have been selected to assess background, down gradient, and source-area (near the IWCS) groundwater quality conditions in the upper groundwater system (Appendix A, Figure 2, page F-2). Groundwater monitoring includes analysis for radioactive constituents, water quality parameters, and metals. The upper groundwater system (Appendix A, Figure 7, page F-7) would provide the earliest indication in the unlikely event of a breach of the IWCS. The lower groundwater system is not monitored because past analytical results and recent Remedial Investigation results indicate there are no groundwater contaminant plumes, or constituents in excess of MCLs, in the lower water-bearing zone.

Surface water and streambed sediment sampling of radioactive constituents is conducted along the drainage ditch system in upstream, onsite, and downstream locations (Appendix A, Figure 2, page F-2) to assess the migration of constituents in these media should any occur.

### 4.0 SURVEILLANCE METHODOLOGY

Under the NFSS environmental surveillance program, standard analytical methods approved and published by USEPA and the American Society for Testing and Materials (ASTM) are used for chemical (i.e., all non-radiological) analyses. The laboratories conducting the radiological analyses adhere to USEPA-approved methods and to procedures developed by the Environmental Measurements Laboratory (EML) and ASTM. A detailed listing of the specific procedures and the data quality objectives for the surveillance program is provided in the Environmental Surveillance Plan (BNI 1996a).

All 2006 environmental surveillance activities at NFSS were conducted in accordance with the Environmental Surveillance Plan (BNI 1996a) and the instruction guides (IGs) listed in Table E in Appendix A (page T-3). The IGs are based on guidelines provided in RCRA Ground Water Monitoring: Draft Technical Guidance (USEPA 1992b); Test Methods for Evaluating Solid Waste, Physical/Chemical Methods (SW-846; USEPA 1992c); and $A$ Compendium of Superfund Field Operations Methods (USEPA 1987).

### 5.0 ANALYTICAL DATA AND INTERPRETATION OF RESULTS

This section presents the data and interpretation of results for the environmental surveillance program at NFSS. Data for 2006 are presented in Tables 2 through 10 (Appendix A). Trend graphs, summarizing analytical results for air, streambed sediment, surface water and groundwater for 2006 and the preceding four years, are presented in Figures 9 through 26 (Appendix A).

In data tables containing analyses for radioactive constituents, some results may be expressed as negative numbers. This phenomenon occurs when the average background activity of the laboratory counting instrument exceeds the measured sample activity. A negative result is generated when the instrument background activity is subtracted from the sample activity. For the purposes of interpretation, all values below the minimum detectable activity (MDA) are interpreted as having an unknown value between zero and the MDA. Therefore, a result below the MDA is referred to as a non-detected result in the text discussion.

Gross data results for surface water, sediment, and groundwater are compared to the USDOE soil guideline limits (for sediment) and DCGs (for surface water and groundwater), and are used in the assessment of potential impact. The analytical results including site background results are provided in the data tables. However, for simplicity of presentation, only the gross analytical results (without the background subtracted) are discussed in the text of this document.

Historical ranges in background concentrations for each radioactive analyte are determined from background sampling results from 1992 to 2006, unless otherwise noted. For gamma dose rates subtracting the calculated background from the sampling results for 2006 then gives an estimate of the above-background dose rate at each location; see Table 2 External Gamma Radiation Dose Rates (Appendix A, page T-7). When background is subtracted from the sampling result, it is possible that a negative number will be obtained much the same as a negative value may be obtained when the laboratory subtracts instrument background from a sample measurement.

Some of the historical data from NFSS used a method for analysis of total uranium, which yields results in $\mu \mathrm{g} / \mathrm{L}$, and $\mu \mathrm{g} / \mathrm{g}$ for water and sediment samples, respectively. To allow direct comparison of results to the DCGs and soil guidelines, the data was converted to $\mathrm{pCi} / \mathrm{L}$ and $\mathrm{pCi} / \mathrm{g}$, as appropriate. The specific activity for total uranium in drinking water sources has been estimated to be about $0.9 \mathrm{pCi} / \mu \mathrm{g}$ (USEPA 2000), which is the factor used to convert groundwater data from $\mu \mathrm{g} / \mathrm{L}$ to $\mathrm{pCi} / \mathrm{L}$ in this report. The specific activity for total uranium in soil sources is estimated to be $0.67 \mathrm{pCi} / \mu \mathrm{g}$ (USEPA 2000).

### 5.1 External Gamma Radiation

External gamma radiation dose rates are measured using thermoluminescent dosimeters (TLDs) continuously for the year. TLD results for the 2006 external gamma radiation dose (both raw and corrected data) are presented in Table 2 (Appendix A, Tables, External Gamma Radiation at NFSS).

The data are used to calculate the external gamma radiation dose rate at both the nearest residence and the nearest commercial/industrial facility to determine the hypothetical maximally exposed off-site individual (MEI). The dose rate is a function of the site fence line dose, the distance of the individual from the fence line, and the amount of time the individual spends at that location. Results of this calculation are expressed as a dose to the individual in mrem for the year.

Distances to off-site receptors are based on the findings of a year 2005 canvas of areas nearby the site. Based on external gamma radiation results, the hypothetical MEI is a resident located 500 feet from the western perimeter fence, southwest of the site that received a dose of 0.014 mrem for calendar 2006. The hypothetical dose to the nearest off-site worker located 1020 feet east of the site is 0.00055 mrem for calendar year 2006 . Appendix B, CY2006 CALCULATION OF EXTERNAL GAMMA RADIATION DOSE RATES FOR NIAGARA FALLS STORAGE SITE (NFSS), section 4.1 contains all pertinent calculations. External gamma dose rates from the NFSS and IWCS perimeters from 2001 thru 2006 are presented in Figures 9 and 10 of Appendix A. Both doses are well below the USDOE guideline of $100 \mathrm{mrem} /$ year (for all pathways, excluding radon).

### 5.2 Radon Gas

Based on the radioactive constituents in the wastes contained in the IWCS, it is unlikely that radon- 220 would be emitted from the IWCS; however, it is possible that radon-222 would be emitted. Air surveillance is conducted to determine the concentration of radon gas at NFSS using Radtrak ${ }^{\circledR}$ detectors that are designed to measure alpha particle emissions from both isotopes of radon (radon-220 and radon-222) and to collect passive, integrated data throughout the period of exposure. Because radon-220 is not a contaminant of concern at NFSS (due to the relatively low concentrations of radium-228 and the short half-life of radon-220), all concentrations are conservatively assumed to be radon-222. Results of semiannual monitoring for 2006 are presented in Table 3 (Appendix A, page 8); the corresponding surveillance locations are shown in Figure 2, Appendix A.

Consistent with results from previous years, most of the site radon-222 results from the 2006 environmental surveillance program were at or below the detection limit of 0.20 $\mathrm{pCi} / \mathrm{L}$. Two background locations reported 0.7 and $0.8 \mathrm{pCi} / \mathrm{L}$ for the first half of the year. Radon concentrations at the NFSS perimeter for the $1^{\text {st }}$ and $2^{\text {nd }}$ half of the year are presented in Figures 11 and 12 respectively. Radon concentrations at the IWCS perimeter
for the $1^{\text {st }}$ and $2^{\text {nd }}$ half of the year are presented by Figures 13 and 14 respectively. All of the on-site results were less than the USDOE off-site limit of $3.0 \mathrm{pCi} / \mathrm{L}$ above background (background ranges from less than 0.2 to $0.8 \mathrm{pCi} / \mathrm{L}$ ).

Radon monitoring at NFSS is performed at a level that is representative of the human breathing zone ( 1.7 meters above ground level). Radon concentration diminishes significantly as distance from the ground increases and mixing with ambient air takes place.

### 5.3 Radon-222 Flux

Measurement of radon-222 flux provides an indication of the rate of radon-222 emission from a surface. Radon-222 flux is measured with activated charcoal canisters placed at $15-\mathrm{m}$ grid across the surface of the IWCS for a 24 -hour exposure period. Measurements for 2006 are presented in Table 4; measurement locations are shown in Figure 2, Appendix A.

Measured results for 2006 ranged from -0.1155 to $0.2115 \mathrm{pCi} / \mathrm{m}^{2} / \mathrm{s}$, with an average result of $0.00717 \mathrm{pCi} / \mathrm{m}^{2} / \mathrm{s}$. Background ranged from -0.062 to .004488 with a average of -0.01848 . As in previous years, these results are well below the $20.0 \mathrm{pCi} / \mathrm{m}^{2} / \mathrm{s}$ standard specified in 40 CFR Part 61, Subpart Q, as well as comparable to background and demonstrate the effectiveness of the containment cell design and construction in mitigating radon-222 migration.

### 5.4 Airborne Particulate Dose

To determine the dose from airborne particulates potentially released from NFSS during 2006, airborne particulate release rates were calculated using Remedial Investigation soil data (collected between 1999 and 2004), and weather data for the year 2006 from the National Weather Service. Data from meteorological stations in the immediate vicinity of the site were not available for CY 2006. Contributions from radon gas, which is not a particulate, are not considered in this calculation. The total airborne particulate release rate is input into the USEPA's CAP88-PC (Version 3.0) computer model to perform two calculations:

1. The first calculation estimates resultant doses from airborne particulates to hypothetical individuals at the distances to the nearest residences and to the nearest commercial/industrial facilities as measured from a central location onsite. Hypothetical doses are then corrected for commercial/industrial facility occupancy at assumed rate of 40 hours/week for 50 weeks/year. Residential occupancy is assumed to be full-time (i.e., 24 hours/day and 365 days/year ( 366 days for a leap year)). The hypothetical individual receiving the higher of these calculated doses is then identified as the hypothetical MEI for airborne particulate dose.
2. The second calculation estimates the hypothetical airborne particulate collective dose to the population within 80 km of the site using a population file ( 2000 census data for New York State and 2001 census data for the Province of Ontario) to determine the number of people in circular grid sections radiating to 80 km from the center of site.

The first calculation (Appendix C) indicates that the 2006 airborne particulate dose to the hypothetical MEI, a home resident, 914 meters south-southwest of the site, was 0.0008 mrem . These values are well below the 10 mrem per year standard, individual dose, specified in 40 CFR, Part 61, Subpart H, and the USDOE Order 5400.5. The second calculation indicates that the hypothetical airborne particulate collective dose to the population within 80 km of the site was 0.024 person-rem. This compares to a yearly background dose to the same population of 3,150,000 person-rem, (see Figure 8, Appendix A). Details of the calculations, including methodology are presented in Appendix C (FUSRAP CY2006 NESHAP ANNUAL REPORT FOR NIAGARA FALLS STORAGE SITE (NFSS)).

### 5.5 Surface Water and Sediment

In 2006, annual surface water and sediment samples were collected at five locations: SWSD009 and SWSD021 at the upstream fence line; SWSD010 and SWSD022 onsite along the central drainage ditch; and SWSD011, downstream along the central drainage ditch. Surface water and sediment sampling location SWSD009 was selected as a background location because it is at the upstream boundary of the South 31 drainage ditch, which eventually joins the central drainage ditch. Surface water and sediment sampling location SWSD021 was selected as a background location because it is located upstream, along the NFSS fence line, where the central drainage ditch first enters the property. Sampling locations are presented in Figure 2, Appendix A.

Surface water and sediment samples were analyzed for radium-226, radium-228, thorium-230, thorium-232, uranium-234, uranium-235, and uranium-238. The 2006 environmental surveillance analytical results for surface water and sediment samples are presented in Appendix A, Tables 5 and 6, respectively. Analytical results for surface water in 2006 are compared with the USDOE DCGs for radium-226, radium-228, thorium-230, thorium-232, and total uranium (sum of the uranium-234, -235 , and -238 isotopes). Because there are no established limits for sediments, USDOE historically used the surface soil criterion of $5 \mathrm{pCi} / \mathrm{g}$ as a basis of comparison of radium-226, radium-228, thorium- 230 and thorium- 232 analytical results, and the derived site-specific criterion of $90 \mathrm{pCi} / \mathrm{g}$ for total uranium in surface soil.

Background concentrations were determined by averaging historical analytical results for the appropriate constituents at surface water/sediment sampling locations SWSD009 and SWSD021. For total uranium and radium-226, background concentrations include data
from 1992 through 2006 for surface water and sediment. Because analysis for thorium-232 first began in 1995 in sediment and 1996 in surface water, background concentrations for thorium-232 were determined from analytical results from 1995 and/or 1996 through 2006, as appropriate. Similarly, background concentrations for radium-228 and thorium-230 were determined from analytical results beginning in 1997.

### 5.5.1 Surface Water

In 2006 as in previous years surface water analytical results were consistently less than the USDOE DCGs, and generally indistinguishable from the historical background (upstream) concentrations. In 2006, surface water analytical results were less than the SDWA MCLs. The 2006 radiological results for the surface water were generally slightly lower or comparable to past results except for the 2004 results for sampling location SWSD010 which were elevated due to the turbidity of the sample. Measured results (with background not subtracted) are provided in Table 5, Appendix A and discussed below:

- The 2006 on-site analytical results for radium- 226 concentrations in surface water are consistent with historical results and are indistinguishable from background. Radium-226 results from upstream (background) locations SWSD009 and SWSD021 were 0.290 and non-detect, respectively, falling within the historical (1997 to present) background range of non-detect to $0.37 \mathrm{pCi} / \mathrm{L}$. The 2006 results of analysis for radium-226 in samples collected at downstream locations (SWSD010, SWSD011, and SWSD022) ranged from non-detect to $0.165 \mathrm{pCi} / \mathrm{L}$. The radium-226 USDOE DCG is $100 \mathrm{pCi} / \mathrm{L}$. Total radium (Ra-226 and Ra-228) concentrations in surface water are below the SDWA limit ( $5 \mathrm{pCi} / \mathrm{L}$ ) and the USDOE DCG $(100 \mathrm{pCi} / \mathrm{L})$, as shown in Figure 15 from 2001 to 2006.
- The 2006 on-site analytical results for radium- 228 concentrations in surface water are consistent with historical results and are indistinguishable from background. Radium228 results from upstream (background) locations SWSD009 and SWSD021 were nondetect and $0.580 \mathrm{pCi} / \mathrm{L}$, respectively comparing favorably with the historical (1997 to present) background range of non-detect to $1.02 \mathrm{pCi} / \mathrm{L}$. The 2006 results for radium228 in samples collected at downstream locations (SWSD010, SWSD011, and SWSD022) ranged from non-detect to $0.240 \mathrm{pCi} / \mathrm{L}$. The radium- 228 USDOE DCG is $100 \mathrm{pCi} / \mathrm{L}$. Total radium (Ra-226 and Ra-228) concentrations in surface water are below the SDWA limit ( $5 \mathrm{pCi} / \mathrm{L}$ ) and the USDOE DCG ( $100 \mathrm{pCi} / \mathrm{L}$ ), as shown in Figure 15 from 2001 to 2006.
- The 2006 results for thorium- 230 in samples collected at downstream locations (SWSD010, SWSD011, and SWSD022) ranged from non-detect to $0.240 \mathrm{pCi} / \mathrm{L}$. Thorium-230 results from upstream (background) locations SWSD009 and SWSD021 were both non-detect, comparing favorably with the historical (1997 to present) background range of non-detect to $1.20 \mathrm{pCi} / \mathrm{L}$ from both background locations.

Historical values for surface water SWSD009 are non-detect to $0.75 \mathrm{pCi} / \mathrm{L}$ which is considered to be more representative of background. The thorium-230 USDOE DCG is $300 \mathrm{pCi} / \mathrm{L}$. Thorium -230 concentrations in surface water are below the adjusted gross alpha MCL SDWA limit of $15 \mathrm{pCi} / \mathrm{L}$ and the USDOE DCG of $300 \mathrm{pCi} / \mathrm{L}$, as shown in Figure 16 from 2001 to 2006.

- The 2006 on-site analytical results for thorium-232 concentrations in surface water were non-detect and $-0.014 \mathrm{pCi} / \mathrm{L}$, compared to background ( 0.00 and non-detect). The historical (1997 to present) background concentration for thorium-232 ranges from non-detect to $0.613 \mathrm{pCi} / \mathrm{L}$. The USDOE DCG for thorium-232 is $50 \mathrm{pCi} / \mathrm{L}$. Thorium232 concentrations in surface water are below the adjusted gross alpha MCL SDWA limit ( $15 \mathrm{pCi} / \mathrm{L}$ ) and the USDOE DCG $(50 \mathrm{pCi} / \mathrm{L})$, as shown in Figure 17 from 2001 to 2006.
- The 2006 on-site analytical results for total uranium in surface water, ranged from 4.46 to $7.09 \mathrm{pCi} / \mathrm{L}$, which compares favorably against the background range of 4.53 and $8.84 \mathrm{pCi} / \mathrm{L}$. The historical (1997 to present) background concentration for total uranium ranges from 1.8 to $25.56 \mathrm{pCi} / \mathrm{L}$ from both background locations or 1.8 to 8.67 $\mathrm{pCi} / \mathrm{L}$ from surface water location SWSD009, which is considered to be more representative of background. Concentrations of total uranium in surface water, Figure 18 , demonstrates a six year trend that is below the SDWA limit of $30 \mu \mathrm{~g} / \mathrm{L}(27 \mathrm{pCi} / \mathrm{L})$, with the exception of SWSD010 in April 2004. That single anomalously elevated sample was attributed to greater turbidity.

### 5.5.2 Sediment

Concentrations of radium-226, radium-228, thorium-230, thorium-232, and total uranium in shallow sediment were less than the USDOE surface soil guidelines and were generally indistinguishable from upstream (background) conditions. At all sampled locations, results were less than the USDOE guideline for mixtures of radionuclides (using the sum-of-the-ratios method). Measured results (with background not subtracted) are presented in Table 6, Appendix A, page T-13, and discussed below:

- The 2006 analytical results for radium-226 in sediment are consistent with historical analytical results. Radium-226 results from upstream (background) locations SWSD009 and SWSD021 were 0.98 and $0.91 \mathrm{pCi} / \mathrm{g}$, respectively, comparing favorably with the historical background range (from 1997 to present) of non-detect to $1.51 \mathrm{pCi} / \mathrm{g}$. The 2006 results of analysis for radium-226 in samples collected at downstream locations (SWSD010, SWSD011, and SWSD022) ranged from 0.63 to $1.70 \mathrm{pCi} / \mathrm{g}$. Historically, the concentration of radium-226 has ranged from non-detect to $2.90 \mathrm{pCi} / \mathrm{g}$. All radium -226 concentrations in sediment were less than the USDOE guideline limit for residual radioactivity in surface soil criterion of $5 \mathrm{pCi} / \mathrm{g}$ above background. In addition, the historic concentrations of total radium (radium-226 and
radium-228) in sediment from 2001 to 2006 were below this criterion as shown in Figure 19.
- The 2006 analytical results for radium-228 in sediment are consistent with historical analytical results. Radium-228 results from upstream (background) locations SWSD009 and SWSD021 were 0.80 and $1.15 \mathrm{pCi} / \mathrm{g}$, respectively. The 2006 results for radium-228 in samples collected at downstream locations (SWSD010, SWSD011, and SWSD022) ranged from 0.85 to $1.19 \mathrm{pCi} / \mathrm{g}$. Historically (from 1997 to present), the background concentration of radium-228 has ranged from non-detect to $2.28 \mathrm{pCi} / \mathrm{g}$ from both background locations or non-detect to $1.15 \mathrm{pCi} / \mathrm{g}$ from sediment location SWSD009, which is considered to be more representative of background. All radium-228 concentrations in sediment were less than the USDOE surface soil cleanup criterion of $5 \mathrm{pCi} / \mathrm{g}$ above background. In addition, the historic concentrations of total radium (radium-226 and radium-228) in sediment from 2001 to 2006 were below this criterion as shown in Figure 19.
- The 2006 analytical results for thorium- 230 in sediment are consistent with historical analytical results. Thorium- 230 results from upstream (background) locations SWSD009 and SWSD021 were 1.32 and $1.25 \mathrm{pCi} / \mathrm{g}$, respectively. The 2006 results for thorium-230 in samples collected at downstream locations (SWSD010, SWSD011, and SWSD022) ranged from 1.03 to $1.26 \mathrm{pCi} / \mathrm{g}$. Historically (from 1997 to present) the background concentration of thorium 230 has ranged from 0.1 to $3.34 \mathrm{pCi} / \mathrm{g}$. All thorium- 230 concentrations in sediment were less than the USDOE Guideline Limit for Residual Radioactivity in Surface Soil. Thorium-230 concentrations in sediment are below the USDOE DCG ( $5 \mathrm{pCi} / \mathrm{g}$ ), as shown in Figure 20 from 2001 to 2006. In addition, the historic concentrations of total thorium (thorium-230 and thorium-232) in sediment from 2001 to 2006 were below this criterion as shown in Figure 20.
- The 2006 analytical results for thorium- 232 in sediment are consistent with historical analytical results. Thorium- 232 results from upstream (background) locations SWSD009 and SWSD021 were 0.99 and $1.12 \mathrm{pCi} / \mathrm{g}$, respectively. The 2006 results for thorium-232 in samples collected at downstream locations (SWSD010, SWSD011, and SWSD022) ranged from 0.86 to $1.05 \mathrm{pCi} / \mathrm{g}$. Historically (from 1997 to present), the background concentration of thorium- 232 has ranged from non-detect to 1.78 $\mathrm{pCi} / \mathrm{g}$. All thorium- 232 concentrations in sediment were less than the USDOE surface soil cleanup criterion of $5 \mathrm{pCi} / \mathrm{g}$ above background. In addition, the historic concentrations of total thorium (thorium-230 and thorium-232) in sediment from 2001 to 2006 were below this criterion as shown in Figure 21.
- The 2006 analytical results for total uranium in sediment are consistent with historical analytical results. Total uranium results from upstream (background) locations SWSD009 and SWSD021 were 2.72 and $2.53 \mathrm{pCi} / \mathrm{g}$, respectively. The 2006 results for total uranium in samples collected at downstream locations (SWSD010, SWSD011,
and SWSD022) ranged from 2.74 to $3.37 \mathrm{pCi} / \mathrm{g}$. Historically (from 1997 to present) the background concentration of total uranium has ranged from 1.8 to $10.10 \mathrm{pCi} / \mathrm{g}$ from both background locations or 1.8 to $5.97 \mathrm{pCi} / \mathrm{g}$ from sediment location SWSD009, which is considered to be more representative of background. All uranium concentrations in sediment were less that the USDOE derived surface soil cleanup criterion of $90 \mathrm{pCi} / \mathrm{g}$ above background. In addition, the historic concentrations of total uranium (uranium-234, uranium-235 and uranium-238) in sediment from 2001 to 2006 were below this criterion as shown in Figure 22.

### 5.6 Groundwater

The locations of environmental surveillance groundwater monitoring wells at NFSS are shown in Figure 2. Background information, descriptions of activities performed under the groundwater surveillance program, and surveillance results are discussed below.

### 5.6.1 Groundwater Flow System

### 5.6.1.1 Natural System

Four unconsolidated geologic units and one bedrock unit are identified in the subsurface at the site. The principle hydrostratigraphic zones include the following, from top to bottom: the Upper Water Bearing Zone (fill, sand lenses, and Upper Brown Clay Till Unit), the aquitard or confining unit (Glacio-Lacustrine Clay and Middle Silt Till Units), and the Lower Water Bearing Zone (Alluvial Sand and Gravel, Basal Red Till, and Upper Queenston Formation). See Figure-7: Schematic of Conceptualized Hydrostratigraphy in Appendix A, page F-7. Groundwater at the NFSS primarily flows in two deposits: the upper water bearing zone in the surficial brown clay till unit and the lower water bearing zone in the combined sand and gravel unit, red till unit, and weathered portion of the Queenston Shale bedrock. Regional groundwater flow in both the upper and lower groundwater systems is to the northwest towards Lake Ontario.

Surface drainage from the site originally entered Fourmile, Sixmile, and Twelvemile Creeks, which all flow northward to Lake Ontario. However during the 1940s, drainage modifications routed surface water to a central drainage ditch that seasonally influences groundwater flow in the upper groundwater system near the IWCS. The current discharge from the central drainage ditch is to Fourmile Creek.

Monitoring wells screened in the upper groundwater system provide an early detection network to monitor the performance of the IWCS, which precludes the lower groundwater system as a monitored zone for the environmental surveillance program. Groundwater wells completed in the lower system were sampled during the recent CERCLA Remedial Investigation (RI), which produced results supporting the programmatic premise that
annual monitoring of this lower groundwater system is not necessary (i.e., RI results indicate a lack of contamination).

Background concentrations for the upper groundwater system were determined by averaging analytical results from 1992 through 1997 for the appropriate constituents at monitoring well B02W20S. This well was selected to represent background because it is distal from and not downgradient of the IWCS. Additional background groundwater was sampled in 2003 from wells hydraulically upgradient from operations at the adjacent property of Modern Landfill. Since this data, compiled for the RI, was comparable to historic groundwater concentrations from B02W20, this well was verified to be representative of background conditions.

### 5.6.1.2 Water Level Measurements

Groundwater levels were measured in ninety-one (91) NFSS wells with an electronic depth-to-water meter. Potentiometric data were recorded from forty-nine (49) wells in the upper ground water system and forty-two (42) wells in the lower groundwater system (including 6 bedrock wells).

The screened intervals for wells completed in the upper groundwater zone range from 1.4 to $8.4 \mathrm{~m}(4.7$ to 27.6 ft$)$ below ground surface, while screened intervals for wells completed in the lower groundwater zone range from 6.8 to 31.9 m ( 22.4 to 104.5 ft ) below ground surface. The ninety-one groundwater monitoring wells are located throughout the NFSS and provide significant areal coverage for groundwater flow characterization. The monitored (sampled) subset of eight (8) wells provide adequate data to assess the IWCS performance and monitor specific areas of concern (Appendix A, Figure 2).

Vertical gradients derived from heads in monitoring well pairs vary with seasonality. Flow from the upper zone to the lower zone was dominant during the first quarterly measurements. However, during the second, third, and fourth quarters, the majority of elevations in the lower system were greater than those measured in the upper system, albeit very slight in some cases. This seasonal variation in the direction and magnitude of vertical gradients will affect vertical flow between water bearing zones and thus affect the long-term transport of potential contaminants by maintaining the upper zone as the primary transport pathway at the NFSS. While groundwater flow is primarily horizontal in these upper and lower zones, the upward vertical gradients help impede the potential for downward migration of contaminants into the lower zone from possible contaminant sources in the upper zone.

In the upper groundwater system, the depth to water ranged from -0.01 to $4.98 \mathrm{~m}(-0.04$ to 16.34 ft ) below ground surface during 2006; the above-ground (negative) level was observed during October, when standing water occupied the ground surface near well 201A due to a significant precipitation event in October. The quarterly water level fluctuations in the upper groundwater system averaged $0.62 \mathrm{~m}(2.05 \mathrm{ft})$ and showed high
and low elevations during the February and August measurements, respectively.

In the lower groundwater system, the depth to water ranged from 0.43 to 2.98 m ( 1.41 to 9.79 ft ) below ground surface during 2006. Quarterly water-level fluctuations in the lower groundwater system averaged $0.27 \mathrm{~m}(0.87 \mathrm{ft})$ and showed high and low elevations during May and October measurements respectively.

Head fluctuations in both the upper and lower water-bearing zones were lower in 2006 than 2005 due to greater precipitation in 2006, which lessened summer-season soilmoisture stresses on the upper zone groundwater. Precipitation data recorded at the Niagara Falls International Airport total 91.4 cm ( 35.99 inches) in 2005 and approximately 98.2 cm (38.66 inches) in 2006.

Water-level data indicate that the upper groundwater system responds more rapidly to the recharge and discharge seasons (wet and dry periods) than the lower confined groundwater system due to the aquitard created by the intervening Glacio-Lacustrine Clay and Middle Silt Till Units. The two water-bearing zones demonstrate hydraulic separation through independent water-level responses, as exemplified by the temporally different seasonal high and low conditions. This two to three month time lag between head extremes indicates that the Glacio-Lacustrine Clay and Middle Silt Till Units form a competent aquitard that governs vertical flow at the NFSS, even where thin (e.g., a 2.5 -foot thickness at wells OW10A and OW10B still produces up to $0.6 \mathrm{~m}(2 \mathrm{ft})$ of head differential between the wells).

Figures 3 through 6 in Appendix A show the piezometric surfaces and groundwater flow directions in the upper and lower units during seasonally high and low groundwater conditions. Groundwater contours initially are hand-drawn to account for site features (e.g., the IWCS and drainage ditches) and then digitized using ArcGIS® to present the groundwater flow directions and gradients in report-quality graphics.

### 5.6.1.3 Groundwater Flow

Water-bearing hydrostratigraphic zones in the layered glacial sediments underlying the NFSS include the upper surficial clay till unit, the lower alluvial sand and gravel, and the weathered bedrock unit (i.e., approximated as the upper 10 feet of bedrock). Groundwaterlevel data indicate that the intervening glaciolacustrine clay unit hydraulically separates the upper clay till unit from the lower sand and gravel unit; this glaciolacustrine clay is present across the entire site. The average horizontal gradients in the upper system range between 0.01 and $0.002 \mathrm{ft} / \mathrm{ft}$ and are dependent on local to regional flow conditions (i.e., flow along the IWCS to the central drainage ditch or more regional gradients across the whole site).

Localized on-site flow towards the central drainage ditch east of the IWCS is consistently apparent due to the unique flow boundary conditions in this area (i.e., IWCS cut-off wall,
low recharge due to a sloped [well drained] land surface, and proximate ditch). The drainage ditches at the NFSS have accumulated sediment and organic matter since their original installation (up to 10 -feet deep); consequently they do not fully penetrate the upper water-bearing zone and some groundwater is assumed to pass beneath the ditches during high-water periods. Water-level contours may be drawn through the ditches to reflect some groundwater flow beneath them. During the summer, vegetation within the ditches will evapotranspire groundwater and further lower local heads near site ditches.

The lower groundwater system generally shows a northerly to northwesterly flow under gradients of 0.003 to $0.004 \mathrm{ft} / \mathrm{ft}$. This flow vector has been affected by the excavation of a clay borrow operation west of the site (mining the Glaciolacustrine Clay), where local surface-water recharges the lower water-bearing zone, which has caused the normally northwestern gradients to have a northerly component during the high-water period (May 2006). The local groundwater low underlying the IWCS is likely a combined artifact of impressed heads to the west, variations in the thickness of the gray clay aquitard and underlying hydrostratigraphic layers, and topography of the Queenston Shale. The longterm impacts from the clay mining will be assessed in future Technical Memorandums.

Dewatering activities in the upper zone to support a waste-cell expansion at Modern Landfill southeast of the NFSS did not affect NFSS wells (i.e., no significant drawdown was evident in 2006).

A groundwater flow velocity of $38 \mathrm{~cm} / \mathrm{yr}$ ( $15 \mathrm{in} / \mathrm{yr}$ ) was estimated at NFSS in 1994 (USDOE 1994b). This velocity does not represent a contaminant migration rate since contaminant-soil partitioning retards (or slows) the rate of contaminat flow (transport) with respect to groundwater flow. This partitioning causes contaminants to adsorb, or bind, to local fine-grained soils in the upper water-bearing zone and aquitard.

Groundwater elevations measured quarterly during 2006 in the upper water-bearing zone show a high condition occurred on February 21, 2006 and a low condition on August 16, 2006. The high-water elevations in the upper system ranged from 94.99 to 97.22 m ( 311.67 to 318.96 ft ) above mean sea level, whereas the low-water condition ranged from 92.46 to 96.81 m ( 303.35 to 317.63 ft ). Groundwater elevations in the lower water bearing zone indicate a seasonal high occurred on May 16, 2006 and a seasonal low occurred on October 17, 2006. The high-water elevation in the lower system ranged from 94.62 to 96.85 m ( 310.43 to 317.74 ft ) above mean sea level, whereas the low-water condition ranged from 93.86 to 96.07 m ( 307.95 to 315.18 ft ). See Figures 3 through 6 in Appendix A for a graphical representation of these data, interpreted groundwater flow directions, and conditions evident from local clay mining west of the NFSS.

### 5.6.2 Groundwater Analytical Results

### 5.6.2.1 Field Parameters

Table 7, Appendix A summarizes field measurements (temperature, pH , specific conductance, oxidation-reduction potential, and turbidity) for 2006 environmental surveillance sampling. These measurements represent water conditions at the time of sampling.

### 5.6.2.2 Water Quality Parameters

At NFSS, water quality in the upper water-bearing zone is indicative of low recharge to a hydraulically slow flow system, which produces poor-quality (near-saline) groundwater containing high total dissolved solids and calcium/magnesium sulfates. Water quality in the lower water-bearing zone is poor due to high total dissolved solids produced by long residence times associated with long (possibly tortuous) flow paths from aerial recharge zones. It is likely that the lower groundwater system receives recharge along the base of the Niagara Escarpment, situated approximately 3.2 km south of the site (USDOE 1994b) and, to a lesser extent, via downward flow from the upper unit during spring recharge. Water quality parameter data for 2006 are provided in Table 8, Appendix A.

Analytical results for sodium, sulfate, and total dissolved solids were consistently above the drinking water standards in both the upgradient (background) and downgradient samples. These values indicate that groundwater in the area is naturally saline and confirm the findings of regional to local studies that state groundwater quality is poor near the site because of high mineralization (La Sala 1968; Wehran 1977; Acres American 1981). Groundwater at NFSS is not used as a public water supply, although the comparison to the drinking water standard will continue to be used to provide a conservative evaluation of groundwater analytical results.

For comparative purposes, the NYSDEC Class GA water quality standards shall be utilized when primary Federal standards are not available. Total dissolved solids (TDS), sulfate, and sodium were present onsite and upgradient (background) in concentrations exceeding NYSDEC Class GA groundwater quality standards. TDS results in all wells including the background well exceed the NYSDEC Class GA and Secondary National Drinking Water Quality standard of $500 \mathrm{mg} / \mathrm{L}$; for example, 2006 TDS data for monitoring wells show OW13B at $2,270 \mathrm{mg} / \mathrm{L}$ (highest annual value) and OW17B at $982 \mathrm{mg} / \mathrm{L}$ (lowest annual value). The on-site background well, B02W20S, produced a TDS value of $905 \mathrm{mg} / \mathrm{L}$ in 2006. Sodium was detected in all wells, including the background well, at concentrations ranging from $38.0 \mathrm{mg} / \mathrm{L}$ to $80.8 \mathrm{mg} / \mathrm{L}$, which are consistently greater than the NYSDEC Class GA groundwater quality standard of $20 \mathrm{mg} / \mathrm{L}$ for sodium. Sulfate was detected in all wells at concentrations ranging from $50.0 \mathrm{mg} / \mathrm{L}$ to $785 \mathrm{mg} / \mathrm{L}$, indicating all but one well had sulfate concentrations greater than the NYSDEC Class GA groundwater quality standard of $250 \mathrm{mg} / \mathrm{L}$.

### 5.6.2.3 Groundwater - Radioactive Constituents

In 2006, unfiltered groundwater samples collected from seven groundwater monitoring wells completed in the upper groundwater system were analyzed for radium-226, radium228, thorium-230, thorium-232, uranium-234, uranium-235, and uranium- 238 . Environmental surveillance analytical results for radioactive constituents in groundwater are presented in Appendix A, Table 9 and Figures 23 through 26. Only results for detected analytes are discussed and used in constituent average values.

Radium- 226 concentrations in groundwater at NFSS have been consistently low, with all measured concentrations (background not subtracted) less than $0.3 \mathrm{pCi} / \mathrm{L}$. Combined concentrations of radium-226 and radium-228 at NFSS are below the SDWA MCL of 5 $\mathrm{pCi} / \mathrm{L}$. Thorium- 230 and thorium -232 concentrations are below USDOE DCGs ( $300 \mathrm{pCi} / \mathrm{L}$ and $50 \mathrm{pCi} / \mathrm{L}$ ) and the SDWA MCL of $15 \mathrm{pCi} / \mathrm{L}$, adjusted gross alpha MCL, for combined thorium- 230 and thorium- 232 in drinking water. The 2006 total uranium analytical results are consistent with the historical results. Total uranium concentrations are below the SDWA MCL $30 \mu \mathrm{~g} / \mathrm{L}$ or $27 \mathrm{pCi} / \mathrm{L}$, with the exception of OW04B and A45. Since 1992, total uranium concentrations in all sampled wells have been less than $60 \mathrm{pCi} / \mathrm{L}$ (background not subtracted), which falls below the USDOE DCG of $600 \mathrm{pCi} / \mathrm{L}$ for water.

All analytical results for radium-226, radium-228, thorium-230, thorium-232, and total uranium in groundwater were well below the USDOE DCGs. At all sampled locations, results were less than the USDOE guideline for mixtures of radionuclides (using the sum-of-the-ratios method). Current analytical results (background not subtracted) are summarized below.

Note: Groundwater at NFSS is not a drinking water source. Samples from all seven wells have unfiltered results for comparison purposes.

- The 2006 total (unfiltered) and filtered ( 0.45 micrometer filter) analytical results for radium- 226 ranged from non-detect to $0.25 \mathrm{pCi} / \mathrm{L}$. The USDOE DCG for radium- 226 is $100 \mathrm{pCi} / \mathrm{L}$ above background and the SDWA MCL for combined radium- 226 and radium- 228 is $5 \mathrm{pCi} / \mathrm{L}$ (2006 background level was non-detect). Total radium (Ra-226 and Ra-228) concentrations in groundwater are below the SDWA limit of $5 \mathrm{pCi} / \mathrm{L}$ and the USDOE DCG of $100 \mathrm{pCi} / \mathrm{L}$, as shown in Figure 23 from 2001 to 2006.
- The 2006 total (unfiltered) and filtered ( 0.45 micrometer filter) analytical results for radium- 228 ranged from non-detect to $0.650 \mathrm{pCi} / \mathrm{L}$. The USDOE DCG for radium228 is $100 \mathrm{pCi} / \mathrm{L}$ above background and the SDWA MCL for combined radium-226 and radium-228 is $5 \mathrm{pCi} / \mathrm{L}$ (2006 background levels was non-detect). Total radium (Ra-226 and Ra-228) concentrations in groundwater are below the SDWA limit (5 $\mathrm{pCi} / \mathrm{L})$ and the USDOE DCG ( $100 \mathrm{pCi} / \mathrm{L}$ ), as shown in Figure 23 from 2001 to 2006.
- The 2006 total (unfiltered) and filtered 0.45 micrometer filter) analytical results for thorium- 230 ranged from non-detect to $0.084 \mathrm{pCi} / \mathrm{L}$. The USDOE DCG for thorium230 is $300 \mathrm{pCi} / \mathrm{L}$ above background and the SDWA MCL for thorium- 230 and thorium-232 is $15 \mathrm{pCi} / \mathrm{L}$, adjusted gross alpha MCL (2006 background levels was nondetect). Thorium- 230 concentrations in groundwater are below the SDWA limit of $15 \mathrm{pCi} / \mathrm{L}$ and the USDOE DCG of $100 \mathrm{pCi} / \mathrm{L}$, as shown in Figure 24 from 2001 to 2006.
- The 2006 total (unfiltered) and filtered ( 0.45 micrometer filter) analytical results for thorium-232 are non-detect and accordingly U-flagged (see Table 9). The USDOE DCG for thorium-232 is $50 \mathrm{pCi} / \mathrm{L}$ above background and the SDWA MCL for thorium- 230 and thorium- 232 is $15 \mathrm{pCi} / \mathrm{L}$, adjusted gross alpha MCL, (2006 background level for thorium - 232 was non-detect). Thorium- 232 concentrations in groundwater are below the SDWA limit of $15 \mathrm{pCi} / \mathrm{L}$ and the USDOE DCG of 50 $\mathrm{pCi} / \mathrm{L}$, as shown in Figure 25 from 2001 to 2006.
- The 2006 total (unfiltered) and filtered ( 0.45 micrometer filter) analytical results for total uranium ranged from 4.42 to $40.42 \mathrm{pCi} / \mathrm{L}$ The USDOE DCG for total uranium is $600 \mathrm{pCi} / \mathrm{L}$ above background (2006 background level was $9.34 \mathrm{pCi} / \mathrm{L}$ ). The USEPA National Primary Drinking Water Regulation for Radionuclides (Final Rule - effective 2003) states the SDWA MCL for total uranium is $30 \mu \mathrm{~g} / \mathrm{L}$ or $27 \mathrm{pCi} / \mathrm{L}$. Two wells exceeded this limit for both the filtered and unfiltered groundwater samples, OW04B filtered sample at $40.42 \mathrm{pCi} / \mathrm{L}$, or $44.90 \mu \mathrm{~g} / \mathrm{L}$, and A45, unfiltered, duplicate sample at $38.12 \mathrm{pCi} / \mathrm{L}$, or $42.36 \mu \mathrm{~g} / \mathrm{L}$. Total uranium concentrations in groundwater are below the USDOE DCG of $600 \mathrm{pCi} / \mathrm{L}$, as shown in Figure 26. Historic total uranium concentrations in groundwater, as shown in Figure 26, are also below the SDWA limit of $27 \mathrm{pCi} / \mathrm{L}$, with the exception of well A45 between 2001 to 2003 and 2006, and well OW04B between 2001 and 2006. However, total uranium concentrations in groundwater in wells A45 and OW04B do not exhibit consistently increasing trends throughout the six year period. Note: The total uranium MCL of $30 \mu \mathrm{~g} / \mathrm{L}$ is for comparative purposes only and includes background

### 5.6.2.4 Groundwater - Chemical Constituents/Metals

The 2006 environmental surveillance analytical results for metals in groundwater are presented in Table 10, Appendix A, and discussed below.

Groundwater at NFSS is not used as a public drinking water supply, although sampling results are compared to the SDWA MCLs and New York State Water Quality Regulation Class GA standards as a conservative baseline. Copper was present in six groundwatermonitoring wells sampled at NFSS, but the 2006 analytical results indicate that neither the SDWA MCLs nor the New York State Water Quality Regulation Class GA standards for
these metals were exceeded at any well. Vanadium and lead were not detected in the eight wells sampled in 2006.

- Copper 2006 total (unfiltered) and filtered ( 0.45 micron filter) analytical results ranged from $1.9 \mu \mathrm{~g} / \mathrm{L}$ to $5.8 \mu \mathrm{~g} / \mathrm{L}$. The SDWA action level is $1,300 \mu \mathrm{~g} / \mathrm{L}$ and the New York State Water Quality Regulation Class GA standard of $200 \mu \mathrm{~g} / \mathrm{L}$. Historically the concentration of copper has ranged from nondetect to $62.4 \mu \mathrm{~g} / \mathrm{L}$.
- Lead 2006 total (unfiltered) and filtered ( 0.45 micron filter) analytical results were non-detect (less than $0.49 \mu \mathrm{~g} / \mathrm{L}$ ). The SDWA action level is $15 \mu \mathrm{~g} / \mathrm{L}$ and the New York State Water Quality Regulation Class GA standard is $25 \mu \mathrm{~g} / \mathrm{L}$. Historically the concentration of lead has ranged from nondetect to $6.8 \mu \mathrm{~g} / \mathrm{L}$.
- Vanadium 2006 total (unfiltered) and filtered ( 0.45 micron filter) analytical results were non-detect (less than $1.6 \mu \mathrm{~g} / \mathrm{L}$ ). Historically the concentration of vanadium has ranged from nondetect to $53.4 \mu \mathrm{~g} / \mathrm{L}$. Neither an SDWA MCL nor a New York State Water Quality Regulation Class GA standard has been established for vanadium.

### 6.0 CONCLUSIONS

### 6.1 External Gamma Radiation

For 2006 the calculated hypothetical doses from external gamma radiation are 0.014 mrem for the nearest resident and 0.00055 mrem for the nearest off-site worker.

### 6.2 Radon Gas

Results of the 2006 radon gas surveillance program indicate radon gas emissions are comparable to background. The radon gas concentrations at the site were consistently low (non-detect to $0.8 \mathrm{pCi} / \mathrm{L}$, including background (Appendix A, Table 3)), and in many cases were at or below the detection limit. All radon gas concentration analytical results at NFSS were well below the USDOE limit for radon-222 of $3.0 \mathrm{pCi} / \mathrm{L}$ above background (Appendix A, Table 3).

### 6.3 Radon-222 Flux

The 2006 radon- 222 flux measurements were indistinguishable from background. Results ranged from non-detect to $0.1162 \mathrm{pCi} / \mathrm{m}^{2} / \mathrm{s}$, with an average (of detects and non-detects) result of $0.00717 \mathrm{pCi} / \mathrm{m}^{2} / \mathrm{s}$ (Appendix A, Table 4). The average value is less than one percent of the standard of $20 \mathrm{pCi} / \mathrm{m}^{2} / \mathrm{s}$ specified in 40 CFR Part 61, Subpart Q of the National Emission Standards for Hazardous Air Pollutants (NESHAPs), demonstrating the effectiveness of the containment cell design and construction in mitigating radon-222 migration.

### 6.4 Airborne Particulate Dose

The 2006 airborne particulate annual dose from the wind erosion of soil to a hypothetical maximally exposed individual is calculated at 0.0008 mrem (Appendix C, FUSRAP CY2006 NESHAP ANNUAL REPORT FOR NIAGARA FALLS STORAGE SITE (NFSS), section 4.3). The hypothetical annual dose to the individual can be compared to the $10 \mathrm{mrem} /$ year dose standard in 40 CFR Part 61, Subpart H of NESHAPs. The 2006 hypothetical airborne particulate annual collective dose to the population within an 80 km radius of the site is calculated at 0.024 person-rem (Appendix C, FUSRAP CY2006 NESHAP ANNUAL REPORT FOR NIAGARA FALLS STORAGE SITE (NFSS), section 5.1).

### 6.5 Cumulative Dose from External Gamma Radiation and Airborne Particulates

The CY 2006 maximum annual total external gamma radiation and airborne particulate dose to a hypothetical individual is $0.015 \mathrm{mrem}[0.014+0.0008$ (assumes same individual
receives both maximum doses from external and airborne dose pathways)], Appendix B, CY2006 CALCULATION OF EXTERNAL GAMMA RADIATION DOSE RATES FOR NIAGARA FALLS STORAGE SITE (NFSS), Section 4.2 and Appendix C, FUSRAP CY2006 NESHAP ANNUAL REPORT FOR NIAGARA FALLS STORAGE SITE (NFSS), Section 4.3, respectively. This value can be compared to the USDOE limit of 100 mrem/year and the US average per capita background dose of approximately 360 mrem/year.

### 6.6 Surface Water

In 2006, onsite radionuclide concentrations in surface water samples were consistent with historical results that indicate no evidence of a release.

### 6.7 Sediment

In 2006, onsite radionuclide concentrations in sediment samples were consistent with historical results that are comparable to background and indicate no evidence of a release.

### 6.8 Groundwater

Current and past onsite radionuclide concentrations in groundwater samples from the upper water bearing zone indicate total uranium levels in excess of background and in some wells the SDWA MCL. The uranium levels are indicative of uranium groundwater contamination caused by past radioactive waste storage practices identified during the remedial investigation and are limited in extent, i.e., generally coincident with historical use areas. Uranium levels in groundwater will continue to be monitored as part of the environmental surveillance program and the on-going CERCLA process will evaluate the extent of uranium in groundwater in excess of background levels and applicable regulatory limits throughout NFSS.

## APPENDIX A

## NFSS 2006 Environmental Surveillance Technical

## Memorandum

## Environmental Monitoring at NFSS

This appendix documents the results of environmental monitoring activities conducted in 2006 and supplements the environmental surveillance information included in the body of this technical memorandum. These activities are described to present a more complete picture of the site activities during the year and to provide technical reviewers with sufficient information to determine how much these activities influenced site conditions and ultimately the environmental surveillance program.

Two distinct activities compose the FUSRAP monitoring program at NFSS: environmental monitoring and environmental surveillance. Environmental monitoring consists of measuring the quantities and concentrations of pollutants in solid wastes, liquid effluents, and air that are discharged directly to the environment from onsite activities. Environmental surveillance documents the effects, if any, of USACE activities on onsite and offsite environmental and natural resources. At FUSRAP sites, because there are typically no onsite waste treatment facilities with routine point discharges, the monitoring program consists primarily of environmental surveillance (BNI 1996). The Environmental Surveillance Technical Memorandum specifically reports the results of routine environmental surveillance sampling and, at applicable sites, includes information about routine environmental monitoring (storm water discharges and radon flux measurement).

From November 1999 to October 2003, surface water, sediment, soil, groundwater, and other media was sampled to support a three-phased Remedial Investigation (RI) at NFSS.

| Combined <br> Radium-226\&228 | $100 \mathrm{pCi} / \mathrm{L}$ | $5 \mathrm{pCi} / \mathrm{L}^{\mathrm{e}}$ | $5 \mathrm{pCi} / \mathrm{g}$ |

a. USDOE derived concentration guide USDOE Order 5400.5) for drinking water. Groundwater at NFSS is not a drinking water source. The above concentration is for comparative purposes only.
b. Surface water and groundwater (non-drinking water values); criteria represent concentrations above background. If a mixture of radionuclides is present, the sum of the ratios of each isotope to its respective DCG must be less than one.
c. Above-background concentrations in soil, averaged over the topmost $15-\mathrm{cm}$ of soil.
d. There are no standards for sediment; therefore, the USDOE residual (radium and thorium) and sitespecific (uranium) surface soil cleanup guideline criteria are used as a basis for evaluating analytical results for sediment. If a mixture of the radionuclides is present in soil, then the sum of the ratios of the concentration of each isotope to the allowable limit must be less than one. This guideline applies for total uranium in natural isotopic abundance.
e. This regulation for uranium of $30 \mu \mathrm{~g} / \mathrm{L}$ became effective December 8, 2003 -National Primary Drinking Water Regulations; Radionuclides; Final Rule (Federal Register-December 7, 2000. Current SDWA MCL for the combined concentration of radium-226 and radium-228 in drinking water is 5pCi/L (40CFR141.1) Groundwater at NFSS is not a drinking water source. The above concentration is for comparative purposes only.
f. "Adjusted" gross alpha MCL of 15 pCi/L, including Th-230, excluding radon and uranium -National Primary Drinking Water Regulations; Radionuclide; Final Rule (Federal Register- December 7,2000)

## Exposure Period 05JAN - 27JUN2006 and 27JUN - 09JAN2007 (Total 369 days)

${ }^{\text {a }}$ All data reported from the vendor were gross results in mrem per monitoring period. Negative values are replaced by the co-located badge value with the exception of the background values.
${ }^{\text {b }}$ Gross data for each period are normalized to a daily dose rate, averaged, and then normalized for the length of the year (365 days)
c Net data are corrected by subtracting the average normalized background value.
${ }^{\text {d }}$ TLD value rejected. Replaced with value from co-located badge.

a. Radon gas concentrations in 2006 were measured with RadTrak ${ }^{\circledR}$ detectors.

These detectors measure the combined concentration of radon-220 and radon-222
in air.
b. $\mathrm{pCi} / \mathrm{L}$ - picocuries per liter.
c. Monitoring locations are shown in Figure 2.
d. Detectors were installed and removed on the dates listed.
e. A quality control duplicate is collected at the same time and location and is analyzed by the same method for evaluating precision in sampling and analysis.
f. Monitoring locations are at the perimeter of the waste containment structure (WCS).

Note: The DOE limit for radon-222 is $3.00 \mathrm{pCi} / \mathrm{L}$ above background.
( <0.2) Indicates detection limit is reported. Actual result is less than this value.
$1 \mathrm{pCi}=0.037$ becquerel

NOTE: The EPA Standard for Radon- 222 Flux is $20 \mathrm{pCi} / \mathrm{m}^{2} / \mathrm{sec}$
a. Radon-222 flux was performed on August 08-09, 2006
b. Every 10th canister is counted twice as a quality control (QC) duplicate to evaluate analytical precision

a. $\mathrm{pCi} / \mathrm{L}$ - picocuries per liter.
b. MDA - Minimum detectable activity.
c. DOE Derived Concentration Guide (DCG) for water.
d. Sum of uranium isotope concentrations.
e. A quality control duplicate is collected at the same time and location and is analyzed by the same method for evaluating precision in sampling and analysis (SWSD011).
f. Validated Qualifier: J - indicates an estimated value.

Validated Qualifier: $\mathbf{U}$ - indicates that no analyte was detected (Non-Detect).

a. $\mathrm{mg} / \mathrm{L}$ - milligrams per liter.
b. Regulations presented pertain to drinking water quality and are listed for comparison only. No drinking water supply is obtained from groundwater at NFSS. NE - Not established.
c. Federal Safe Drinking Water Act maximum contaminant levels from EPA Drinking Water Regulations and Health Advisories (October 1996).
d. Water Quality Criteria (class GA) per 6 NYCRR, Part 703.
e. A quality control (QC) duplicate is collected at the same time and location and is analyzed by the same method for evaluating precision in sampling and analysis.
f. Validated Qualifier: $\mathbf{U}$ - indicates that no analyte was detected above reporting limit (Non-Detect)

Validated Qualifier: $\mathbf{J}$ - indicates an estimated value.

a. Results reported with ( $\pm$ ) radiological error quoted at 2-sigma (95 percent confidence level).
b. $\mathrm{pCi} / \mathrm{L}$ - picocuries per liter.
c. Validated Qualifier: $\mathbf{U}$ - indicates that no analyte was detected (Non-Detect) Validated Qualifier: J - indicates an estimated value.
d. DOE derived concentration guide for water.
e. Sum of uranium isotope concentrations.
f. A quality control duplicate is collected at the same time and location and is analyzed by the same method for evaluating precision of sampling and analysis.
g. Sum of radium isotope concentrations.
h. Not included in averages for Section 5.6.2.3

### 1.0 PURPOSE

This calculation estimates the external gamma radiation dose from the Niagara Falls Storage Site (NFSS), Lewiston, New York (see Figure 1, Appendix A), during calendar year 2006 (CY2006). Hypothetical doses from external gamma radiation to members of the public are calculated from dose measurements using thermoluminescent dosimeters (TLDs) located at the perimeters of the NFSS and the Interim Waste Containment Structure (IWCS) (see Figure 2, Appendix A).

### 2.0 ASSUMPTIONS

Doses were calculated for off-site receptors based on these locations for off-site receptors based on the canvas of receptors in CY2006. The hypothetical doses for the nearest resident and off-site worker are reported. The modeling approach described below is considered to be protective of human health (conservative) in calculating hypothetical dose to receptors. The shielding effect of the air has not been included in the calculations. Calculations for the hypothetical annual external gamma radiation doses to the nearest resident and nearest off-site workerused the following assumptions:

Distance from each TLD above the source (the ground) is 3 feet ( ft ), Distance from the TLDs to the nearest resident is 500 ft (perpendicular to the western TLD line), Distance from the TLDs to the nearest off-site worker is $1,020 \mathrm{ft}$ (perpendicular to the eastern TLD line),
Length of the western TLD monitoring line (western perimeter fence) is $2,766 \mathrm{ft}$, Length of the eastern TLD monitoring line (east of Campbell Street) is 2,700 ft.

## $3.0 \quad$ TLD DATA

At NFSS, TLDs are used to measure gamma radiation from the site and from sources of background radiation. Natural sources of background radiation include cosmic radiation and terrestrial radiation sources. In the United States, the annual average (per capita) cosmic and terrestrial radiation doses are 27 millirem per year (mrem/yr) and $28 \mathrm{mrem} / \mathrm{yr}$, respectively (NCRP Report 93). Annual doses due to background at NFSS are measured at background locations using TLDs. Background dose for the same period of exposure is subtracted from site dose values to estimate the net dose from NFSS. TLDs are located at the facility perimeter and at the perimeter of the IWCS. The TLDs are placed at approximately 3 ft [1.6 meters (m)] above the ground surface. The TLDs measure approximately six-month intervals and are analyzed at an off-site vendor.

Eleven locations around the perimeter of the site and six locations around the IWCS were monitored in CY2006 (see Figure 2, Appendix A). In addition to these locations, there were three background locations (Figure 1, Appendix A). Two environmental TLDs were placed at each monitoring location. The environmental program utilizes two TLDs at each monitoring location for each monitoring period as a quality control check. In addition, if a measurement result is rejected or a TLD is lost, the duplicate reading is assumed for that monitoring period.

TLD monitoring data for CY2006 are presented in Table 2 in the Tables section. A time-weighted or normalized annual dose is calculated that accounts for exposure periods having different integration times (a different number of measurement days). Negative net values are retained for calculation purposes.

### 4.0 ASSESSMENT METHODOLOGY AND RESULTS

Gamma radiation measured at the perimeter fence line represents the dose for full-time occupancy i.e. 24 hours/day and 365 days/year ( 366 days for a leap year). Dose to an off-site receptor is significantly affected by proximity to the source and the amount of time spent at the receptor location. The estimate of dose to an off-site worker therefore uses a correction factor for occupancy assuming 2000 hours worked per year. The estimate of dose to an off-site resident assumes a full-time occupancy at home. The average net dose rate for CY 2006 at the site perimeter by direction is calculated to be:

| Direction | TLD Locations | Calculated Average Net Dose <br> Rate (mrem/year) |
| :--- | :---: | :---: |
| North Perimeter | $1,11,12$, and 122 | 4.91 |
| East Perimeter | $1,28,123$ | 4.30 |
| South Perimeter | 7,28, and 29 | 6.40 |
| West Perimeter | $11,13,15,29,36,8,10$ | 2.47 |

### 4.1 NEAREST RESIDENT

The dose calculation for the nearest resident, uses the line of TLDs along the western perimeter fence. The TLDs along this side of the facility include NFSS perimeter fence monitoring locations 11, 13, 15,29 , and 36 , and WCS perimeter fence monitoring locations 8 and 10 . The two WCS locations are located close to the western NFSS perimeter fence. These TLD locations are shown in Appendix A, Figure 2. Net dose rates (corrected for background) for these TLDs are summed and divided by the total number of observations (14 for CY2006). This average value represents the annual dose at the site perimeter ( $\mathrm{D} 1=2.98 \mathrm{mrem}$ for CY 2006 ). The dose contribution to this resident from the southern exposure is insignificant compared to the exposure from the western line source The western site perimeter dose is then used in the following equation for a line source:

$$
\mathrm{D}_{2}=\mathrm{D}_{1} * \mathrm{~h}_{1} / \mathrm{h}_{2} *\left(\operatorname{ArcTan}\left(\mathrm{~L} / \mathrm{h}_{2}\right) / \operatorname{ArcTan}\left(\mathrm{L} / \mathrm{h}_{1}\right)\right)
$$

```
where:
    D
    D
    h
    \mp@subsup{h}{2}{}}\quad= the distance of the resident from the fence line ( 500 ft)
    L = half the length of line of TLDs measuring the line source (1,383 ft)
```

## Nearest Resident Dose Calculation (Resident southwest of NFSS)

NFSS Perimeter Monitoring Locations 11, 13, 15, 29, and 36 and IWCS Perimeter Monitoring Locations 8 and 10
$\mathrm{h}_{1}=3$ feet distance of TLD from the source
$\mathrm{h}_{2}=500$ feet distance of resident from the TLDs
$\mathrm{L}=1,383$ feet half the length of the western line source
$\mathrm{D}_{1}=2.98 \mathrm{mrem}$ average annual dose at the TLD monitoring locations
$\mathrm{D}_{2}=0.014$ mrem resident annual dose at 500 feet from the TLD
The hypothetical dose to the nearest resident is $1.4 \mathrm{E}-02$ (or 0.014 ) mrem for calendar year 2006.

### 4.2 NEAREST OFF-SITE WORKER

The dose to the nearest off-site worker uses, the line of TLDs,closest to the eastern perimeter fence (Castle Garden Road). The TLDs used include monitoring locations 1, 28, and 123. These TLDs are located along an interior fence east of Campbell Street. Their locations are shown in Figure 2, Appendix A. There are no WCS perimeter fence monitoring locations in close to those along the line east of Campbell Street; therefore, none are included in the dose calculations. Net dose rates (corrected for background) for TLD monitoring locations 1,28 , and 123 are summed and divided by the total number observations ( 6 for CY2006). This average represents the annual dose at the site perimeter ( $\mathrm{D} 1=1.4 \mathrm{mrem}$ for CY2006).

Nearest Off-Site Worker Dose Calculations (Worker east of NFSS)
NFSS Perimeter Monitoring Locations 1, 28, 123
$h_{1}=3$ feet distance of TLD from the source
$\mathrm{h}_{2}=1,020$ feet distance of off-site worker from the TLDs
$\mathrm{L}=1,350$ feet half the length of the eastern line source
$\mathrm{D}_{1}=1.4$ mrem average annual dose at the TLD monitoring locations
$\mathrm{D}_{2}=0.00055$ mrem off-site worker annual dose at 1,020 feet from the TLD location Using the equation above) and a correction factor for off-site worker occupancy of 2000/8760 hours the hypothetical dose to the nearest off-site worker is $5.5 \mathrm{E}-04$ (or 0.00055 ) mrem for calendar year 2006.

### 1.0 INTRODUCTION

In 1974, the United States Atomic Energy Commission (USAEC), a predecessor to the United States Department of Energy (USDOE), instituted the Formerly Utilized Sites Remedial Action Program (FUSRAP). This program is now managed by United States Army Corps of Engineers (USACE) to identify and clean up, or otherwise control sites where residual radioactivity remains from the early years of the nation's atomic energy program or from commercial operations causing conditions that Congress has authorized USACE to remedy under FUSRAP. The Niagara Falls Storage Site (NFSS) is a federally-owned storage site managed under FUSRAP. In October 1997, Congress transferred the responsibility for FUSRAP from USDOE to USACE.

### 1.1 SITE DESCRIPTION

The Niagara Falls Storage Site (NFSS) is located in the Town of Lewiston in northwestern New York State, northeast of Niagara Falls and south of Lake Ontario (Figure 1Appendix A). NFSS is approximately 77 hectare ( $\sim 191$ acre) site which includes: one former process building (Building 401), one office building (Building 429), an equipment shed, and a 4 hectare ( 9.9 acre) interim waste containment structure (IWCS). The property is fenced, and public access is restricted.

Land use in the region is primarily rural; however, the site is bordered by a chemical waste disposal facility on the north, a solid waste disposal facility on the east and south, and a Niagara Mohawk Power Corporation right-of-way on the west. The nearest residential areas are approximately $1.1-\mathrm{km}$ southwest of the site; the residences are primarily single-family dwellings.

### 1.2 SOURCE DESCRIPTION

Beginning in 1944, NFSS was used as a storage facility for radioactive residues and wastes. The residues and wastes are the process by-products of uranium extraction from pitchblende (uranium ore). Waste was also generated from remediation of buildings and process equipment used in the uranium extraction process. The residues originated at other sites and were transferred to NFSS for storage in buildings, on-site pits, and surface piles. Table 1 includes a brief history and description of the major radioactive residues and wastes transferred to NFSS. From 1953 to 1959 and 1965 to 1971, Building 401 was used as a boron-10 isotope separation plant.

Table 1. History and Description of Wastes Transferred to NFSS

| Material | Description | Transferred to <br> NFSS |
| :---: | :--- | :---: |
| L-50 | Low-activity radioactive residues from the processing of low-grade uranium ores at <br> Linde Air Products, Tonawanda, New York. | 1944 |
| R-10 | Low-activity radioactive residues from the processing of low-grade uranium ores at <br> Linde Air Products, Tonawanda, New York. | 1944 |
| F-32 | Low-activity radioactive residues from the processing of high-grade uranium ores at <br> Middlesex, New Jersey. | 1944 to <br> early 1950 |
| L-30 | Low-activity radioactive residues from the processing of low-grade uranium ores at <br> Linde Air Products, Tonawanda, New York. | 1945 |
| K-65 | High-activity radioactive residues from the processing of high-grade uranium ores at <br> Mallinckrodt Chemical Works, St. Louis, Missouri. | 1949 |
| Middlesex <br> Sands | Sand and abraded material from the sandblasting of buildings and process equipment <br> where the F-32 residue was generated at Middlesex Metal Refinement Plant, <br> Middlesex, New Jersey. | 1950 |

Since 1971, activities at NFSS have been confined to residue and waste storage and remediation. All on-site and off-site areas with residual radioactivity exceeding USDOE guidelines were remediated between 1981 and 1992. The materials generated during remedial actions (approximately $195,000 \mathrm{~m}^{3}$ ) are encapsulated in the IWCS (See Appendix A, Figure 2), which is specifically designed to provide interim storage of the materials. Remedial investigation began at the end of 1999 to determine if any areas of the site contained radioactive or chemical contaminants at levels that could pose an unacceptable risk to human health and the environment. Initial results show that isolated areas of elevated activity do exist.

### 2.0 REGULATORY STANDARDS

The United States Environmental Protection Agency's (USEPA) National Emission Standards for Hazardous Air Pollutants (NESHAP) are compliance standards that require annual reporting of emissions of radionuclides and radon gas from operations at nuclear facilities.

### 2.1 40 CFR 61, SUBPART H

40 CFR 61, Subpart H provides standards for reporting emissions of radionuclides (excluding radon-222 and radon-220) into the air from USDOE facilities. Although control and maintenance of the site currently rests with USACE, responsibility for NFSS will return to USDOE following completion of remedial actions. This regulation therefore provides an appropriate standard for NFSS. Compliance with Subpart H is verified by applying the USEPA approved code, CAP88-PC. CAP88-PC Version 3.0 (USEPA 2006)] was used for this years calculation. The applicable regulation, 40 CFR 61.92 limits exposure of the public to effective dose equivalent of $10 \mathrm{mrem} / \mathrm{yr}$ from radioactive emissions.

### 2.2 40 CFR 61, SUBPART Q

40 CFR 61, Subpart Q applies to storage and disposal facilities for radium-containing material that emits radon-222 into air. NFSS is specifically identified as one such facility in this subpart (in 40 CFR 61.190). Compliance with Subpart Q is verified by annual monitoring of the IWCS for radon-222 flux. Subpart Q limits radon-222 emission to $20 \mathrm{pCi} / \mathrm{m}^{2} / \mathrm{s}$.

### 3.0 AIR EMISSION DATA

Table 2 summarizes the sources of air emissions. Attachment A contains the annual wind erosion emission ( $\mathrm{E}_{\mathrm{w}}$ ) calculation. Attachment B contains the source term calculations and annual air releases.

These calculations use the USEPA air pollution emission factor methodology (AP-42) to estimate the radioactive release from wind erosion, which is then used as the source term in the Clean Air Act Assessment Package (CAP88-PC) model to estimate airborne doses to hypothetically exposed individuals. The annual wind erosion emission estimate uses the most current soil data from the NFSS RI sampling Phases I, II, and III. A 95\% upper confidence limit (UCL) without the subtraction of background radioactivity, was calculated for each soil nuclide of concern and used for the 2006 year source term estimate. The area of the entire NFSS was assumed to be uniformly contaminated and to contribute to the source term.

Table 2. Air Emission Data - NFSS

| Point Sources | Type Control | Efficiency | Distance to Hypothetical Exposed Individual |
| :---: | :---: | :---: | :---: |

| Group Sources | Type Control | Efficiency | Distance to Hypothetical Exposed Individual |
| none | not applicable | not applicable | not applicable |

### 4.0 DOSE ASSESSMENTS

### 4.1 MODEL SOURCE DESCRIPTION

To determine the dose from airborne particulates potentially released from NFSS during CY2006, the annual wind erosion emission, $\mathrm{E}_{\mathrm{w}}$ (Attachment A ) is calculated using local climatological data (Attachment F) from the National Oceanic and Atmospheric Administration (NOAA) National Climatic Data Center for the Niagara Falls International Airport (NFIA) in Niagara Falls, NY. Data from an on-site meteorological station at Modern Landfill (ML) in Lewiston, NY was not available for this year. $\mathrm{E}_{\mathrm{w}}$ is calculated using the USEPA AP-42 methodology for "fugitive emissions" from an "area source" that uses the "fastest mile" wind speed data from local climatological data reports. $\mathrm{E}_{\mathrm{w}}$, in grams emitted, is then applied to the soil nuclide concentration to estimate the source term or annual emissions for each radionuclide. The soil concentration was developed from sample data compiled during Phases I, II, and III of the Remedial Investigation for soil contamination (Attachment B). Contributions from radon gas, in accordance with regulatory guidance, are not considered in this calculation. Annual estimated emissions for each radionuclide were input into the USEPA's CAP88-PC, Version 3.0 code to calculate hypothetical receptor doses. The model estimates resultant doses from airborne particulates to hypothetical individuals at the distances to the nearest residence, commercial/industrial facility, school, and farm as measured from a central location on-site. Hypothetical doses are then corrected for occupancy .Commercial/industrial facility and school occupancy is assumed to be $40 \mathrm{hr} /$ week for 50 weeks/yr). Residential and farm occupancy is assumed to be full-time for $24 \mathrm{hr} / \mathrm{day}$ for 365 days/yr. The hypothetical individual receiving the higher of these calculated doses is then identified as the maximally exposed individual (MEI) for airborne particulate dose.

### 4.2 DESCRIPTION OF DOSE MODEL

### 4.2.1 CAP88-PC Computer Program

The CAP88-PC model is a set of computer programs, databases, and associated utility programs that estimate the dose and risk from airborne radioactivity emissions. The USEPA NESHAP compliance procedures for airborne radioactivity emissions at USDOE facilities (40 CFR 61.93(a)) require the use of the CAP88-PC model, or other approved procedures to calculate effective dose equivalents to members of the public.

CAP88-PC uses a modified Gaussian plume equation to estimate the average dispersion of radionuclides released from a site. Assessments are performed for a circular grid of distances and directions for a radius of 80 km ( 50 miles) around the facility. Agricultural arrays of milk cattle, beef cattle and agricultural crop area are generated automatically, requiring the user to supply only the State name or agricultural productivity values. Dose and risk factors for CAP88-PC, Version 3.0 are from Federal Guidance Report 13 and are based on the methods detailed in International Commission on Radiological Protection (ICRP) 72 (ICRP72) The dose calculations presented in this document used the default values for nuclide lung clearance type. These defaults correspond to the recommended values from FGR 13. Deposition velocity and scavenging coefficient are calculated by the code in accordance with USEPA policy. In the CAP88 model nuclides are depleted from the plume by precipitation scavaging, dry deposition and radioactive decay. The default scavenging coefficient is calculated as a function of annual precipitation. The program calculates the effective dose equivalents received by receptors by combining the inhalation and ingestion intake rates and the air and ground surface concentrations using the appropriate dose conversion factors.

### 4.2.2 CAP88-PC Input

Input parameters for CAP88 include:
Radionuclide emissions (Attachment B), Weather data (average annual temperature, total annual precipitation) (Attachment F ), Emission source height and area (Section 4.3), and
Distance to nearest resident, off-site worker, school, and farm (Section 4.3).

### 4.2.3 CAP88-PC Output

The "Dose and Risk Equivalent Summaries" from CAP88-PC contains the resulting effective dose equivalents for each modeled scenario. The effective dose equivalent summary contains results for 16 compass directions around the facility for the nearest resident, off-site worker, school, and farm. CY2006 CAP88-PC individual receptor and population output summaries are located in Attachment C and D, respectively.

### 4.3 COMPLIANCE ASSESSMENT

The released activity data from Attachment B is entered into the CAP88-PC modeling program to derive the hypothetical dose to the defined receptors. To derive the dose to the MEI, the CAP88-PC model must have weather data for the appropriate year, information on the emission source, and the distances and directions to the nearest residence, off-site worker, school, and farm. The following CY2006 meteorological data were entered into CAP88-PC (see Attachment E):

| Average temperature | $10.1^{\circ} \mathrm{C}\left(50.14^{\circ} \mathrm{F}\right)$ NFIA, |
| :--- | :--- |
| Precipitation, | $98.2 \mathrm{~cm}(38.66$ inches $) \mathrm{ML}$, and |
| Mixing height | $1,000 \mathrm{~m}$. |

The following emission source and nearest receptor distances and direction information were also entered into the program:

| Source height | 0 m, |
| :--- | :--- |
| Source area | $780,000 \mathrm{~m}^{2}$, |
| Resident | 914 m SSW |
| Resident (farm) | 1105 m S |
| Resident | 1250 m WSW |
| Resident | 1486 m ESE, |
| Off-site worker | 533 m SE, |
| Off-site worker | 783 m S |
| School (building) | 2499 m W |
| School(building) | 2629 m WNW |

The CAP88-PC annual hypothetical dose to the nearest resident, off-site worker, school, and farm at the corresponding directions and distances taken from page six of the "Dose and Risk Equivalent Summaries" document for individual modeling (Attachment C) are:

| Resident | $8.0 \mathrm{E}-04 \mathrm{mrem}, \mathrm{SSW}$ @ 914 m, |
| :--- | :--- |
| Off-site worker | $3.4 \mathrm{E}-03 \mathrm{mrem}, \mathrm{SE}$ @ 533 m |
| School | $3.1 \mathrm{E}-04 \mathrm{mrem}, \mathrm{W} @ 2499 \mathrm{~m}$ and |
| Farm | $6.1 \mathrm{E}-04 \mathrm{mrem}, \mathrm{S} @ 1105 \mathrm{~m}$. |

The hypothetical doses to the nearest off-site worker and school corrected for $2,000 \mathrm{hr}$ of exposure per year are:

| Off-site worker | 7.8 E-04 mrem and |
| :--- | :--- |
| School | 7.1 E-05 mrem. |

### 5.0 SUPPLEMENTAL INFORMATION

### 5.1 POPULATION DOSE

The CAP88-PC model was also used to estimate the hypothetical airborne particulate dose to the population within 80 km of the site. Population data taken from year 2000 census data for New York State and 2001 census data for Ontario, Canada was used to create a population file for CAP88-PC. The effective dose equivalent for the collective population in person-rem/yr is from the CAP88-PC "Dose and Risk Equivalent Summaries" report.

The CAP88-PC annual effective dose for the population within 80 km of the facility (Attachment D) is:

Population: $\quad 2.4$ E-02 person-rem

### 5.2 RADON-222 FLUX

Measurement of radon-222 flux provides an indication of the rate of radon-222 emission from a surface. Radon- 222 flux is measured with activated charcoal canisters placed at $15-\mathrm{m}$ intervals across the surface of the IWCS for a $24-\mathrm{hr}$ exposure period. Measurements for CY2006 are presented in Table 4; measurement locations are shown in Appendix A, Figure 2.

Measured results for CY2006 ranged from non-detect to $0.126 \mathrm{pCi} / \mathrm{m}^{2} / \mathrm{s}$, with an average value of $0.029 \mathrm{pCi} / \mathrm{m}^{2} / \mathrm{s}$. As in previous years, these results are well below the 20 $\mathrm{pCi} / \mathrm{m}^{2} / \mathrm{s}$ standard specified in 40 CFR Part 61 , Subpart Q , and demonstrate the effectiveness of the containment cell design and construction in mitigating radon-222 migration.

### 5.3 NON-APPLICABILITY

Requirements from section 61.93(b) of 40 CFR for continuous monitoring from point sources (stacks or vents) are not applicable to NFSS.

ATTACHMENT A
ANNUAL WIND EROSION EMISSION CALCULATION

## A. 1 ANNUAL WIND EROSION

In 2006, the potential source of airborne emissions from NFSS is assumed to be from wind erosion of in-situ soil from the entire NFSS. The AP-42 model for industrial wind erosion for limited flat sources is used. In this model the potential airborne emissions are a function of the number of disturbances of contaminated soil. The following assumptions and calculations are made:

The air release source is wind erosion of in-situ soil from an area (A) of $780,000 \mathrm{~m}^{2}$ of vegetation covered soil.

$$
\mathrm{A}=780,000 \mathrm{~m}^{2}
$$

The calculation assumes that $90 \%$ of this area is covered by grass or vegetation (V).

$$
\mathrm{V}=0.90
$$

For CY 2006 there is assumed to have been weekly grass cutting for half the year, occurring May through October and an April spring thaw. The number of estimated disturbances ( N ) is therefore:

$$
\mathrm{N}=27
$$

The threshold velocity $\left(\mathrm{U}_{\mathrm{t}}\right)$ for overburden (USEPA 1995 Table 13.2.5-2) is:

$$
\mathrm{U}_{\mathrm{t}}=1.02 \mathrm{~m} / \mathrm{s}
$$

Anemometer height adjustment is not necessary.
$\mathrm{Z}_{\mathrm{r}}=$ reference anemometer height $=10 \mathrm{~m}$
$\mathrm{Z}_{\mathrm{a}}=$ actual anemometer height $=10 \mathrm{~m}$
The roughness height for overburden is 0.3 cm (USEPA 1995 Table 13.2.5-2).

$$
\mathrm{Z}_{\mathrm{o}}=0.3 \mathrm{~cm}
$$

The corrected wind speed ( $\mathrm{U}_{\mathrm{rN}}$ ) for each period (N) between disturbances (USEPA 1995 Equation 5) is:

$$
\mathrm{U}_{\mathrm{rN}}=\mathrm{U}_{\mathrm{aN}}\left[\ln \left(\mathrm{Z}_{\mathrm{r} /} \mathrm{Z}_{\mathrm{o}}\right) / \ln \left(\mathrm{Z}_{\mathrm{a} /} \mathrm{Z}_{\mathrm{o}}\right)\right] \text {, therefore } \mathrm{U}_{\mathrm{rN}}=\mathrm{U}_{\mathrm{aN}}
$$

The equivalent friction velocity $\left(\mathrm{U}_{\mathrm{N}}\right)$ for each period between disturbances (USEPA 1995 Equation 4) is:

$$
\mathrm{U}_{\mathrm{N}}=0.053 \mathrm{U}_{\mathrm{rN}}
$$

The fastest mile speeds (maximum 2-minute wind speeds ${ }^{\text {a }}$ ) from Local Climatological Data reports from NOAA for Niagara Falls International Airport (NFIA) in mph for the period between each disturbance are:

| $\mathrm{U}_{\mathrm{a} 1}=39$ | $\mathrm{U}_{\mathrm{a} 2}=22$ | $\mathrm{U}_{\mathrm{a} 3}=26$ | $\mathrm{U}_{\mathrm{a} 4}=32$ | $\mathrm{U}_{\mathrm{a} 5}=22$ | $\mathrm{U}_{\mathrm{a} 6}=20$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{U}_{\mathrm{a} 7}=28$ | $\mathrm{U}_{\mathrm{a} 8}=26$ | $\mathrm{U}_{\mathrm{a} 9}=24$ | $\mathrm{U}_{\mathrm{a} 10}=32$ | $\mathrm{U}_{\mathrm{a} 11}=24$ | $\mathrm{U}_{\mathrm{a} 12}=26$ |
| $\mathrm{U}_{\mathrm{a} 13}=35$ | $\mathrm{U}_{\mathrm{a} 14}=39$ | $\mathrm{U}_{\mathrm{a} 15}=29$ | $\mathrm{U}_{\mathrm{a} 16}=23$ | $\mathrm{U}_{\mathrm{a} 17}=29$ | $\mathrm{U}_{\mathrm{a} 18}=17$ |
| $\mathrm{U}_{\mathrm{a} 19}=30$ | $\mathrm{U}_{20}=21$ | $\mathrm{U}_{\mathrm{a} 21}=21$ | $\mathrm{U}_{\mathrm{a} 22}=31$ | $\mathrm{U}_{\mathrm{a} 23}=29$ | $\mathrm{U}_{\mathrm{a} 24}=26$ |
| $\mathrm{U}_{\mathrm{a} 25}=36$ | $\mathrm{U}_{\mathrm{a} 26}=25$ | $\mathrm{U}_{\mathrm{a} 27}=38$ |  |  |  |

${ }^{\text {a }}$ Maximum 2-minute wind speeds can be used to approximate fastest mile wind speeds (USEPA 2004 Table 7-4), however, this calculation applies an uncertainty correction factor, protective of human health, of 1.3 in order to approximate the fastest mile wind speeds.

The equivalent friction velocity in $\mathrm{m} / \mathrm{s}$ for each period is:

| $\mathrm{U}_{1}=1.20 \mathrm{E} 00$ | $\mathrm{U}_{2}=6.78 \mathrm{E}-01$ | $\mathrm{U}_{3}=8.01 \mathrm{E}-01$ | $\mathrm{U}_{4}=9.86 \mathrm{E}-01$ | $\mathrm{U}_{5}=6.78 \mathrm{E}-01$ | $\mathrm{U}_{6}=6.16 \mathrm{E}-01$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{U}_{7}=8.62 \mathrm{E}-01$ | $\mathrm{U}_{8}=8.01 \mathrm{E}-01$ | $\mathrm{U}_{9}=7.39 \mathrm{E}-01$ | $\begin{aligned} & \mathrm{U}_{10}=9.86 \mathrm{E}- \\ & 01 \end{aligned}$ | $\begin{aligned} & \mathrm{U}_{11}=7.39 \mathrm{E}- \\ & 01 \end{aligned}$ | $\mathrm{U}_{12}=8.01 \mathrm{E}-01$ |
| $\mathrm{U}_{13}=1.08 \mathrm{E} 00$ | $\begin{aligned} & \begin{array}{l} \mathrm{U}_{14}=1.20 \\ \mathrm{E}+00 \end{array} \end{aligned}$ | $\begin{aligned} & \mathrm{U}_{15}=8.93 \mathrm{E}- \\ & 01 \end{aligned}$ | $\begin{aligned} & \mathrm{U}_{16}=7.08 \mathrm{E}- \\ & 01 \end{aligned}$ | $\begin{aligned} & \mathrm{U}_{17}=8.93 \mathrm{E}- \\ & 01 \end{aligned}$ | $\begin{aligned} & \mathrm{U}_{18}=5.24 \mathrm{E}- \\ & 01 \end{aligned}$ |
| $\begin{array}{\|l} \hline \mathrm{U}_{19}=9.24 \mathrm{E}- \\ 01 \\ \hline \end{array}$ | $\begin{aligned} & \mathrm{U}_{20}=6.47 \mathrm{E}- \\ & 01 \end{aligned}$ | $\begin{aligned} & \mathrm{U}_{21}=6.47 \mathrm{E}- \\ & 01 \end{aligned}$ | $\begin{aligned} & \mathrm{U}_{22}=9.55 \mathrm{E}- \\ & 01 \end{aligned}$ | $\begin{aligned} & \mathrm{U}_{23}=8.93 \mathrm{E}- \\ & 01 \end{aligned}$ | $\mathrm{U}_{24}=8.01 \mathrm{E}-01$ |
| $\mathrm{U}_{25}=1.11 \mathrm{E} 00$ | $\begin{aligned} & \mathrm{U}_{26}=7.70 \mathrm{E}- \\ & 01 \end{aligned}$ | $\mathrm{U}_{27}=1.17 \mathrm{E} 00$ |  |  |  |

The erosion potential $\left(\mathrm{P}_{\mathrm{N}}\right)$ for a dry exposed surface (USEPA 1985 Figure 4-2) is:

$$
\mathrm{P}_{\mathrm{N}}=58\left(\mathrm{U}^{*}-\mathrm{U}_{\mathrm{t}}\right)^{2}+25\left(\mathrm{U}^{*}-\mathrm{U}_{\mathrm{t}}\right)=22.27 \mathrm{~g} / \mathrm{m}^{2}
$$

The erosion potentials $\left(\mathrm{P}_{\mathrm{N}}\right)$ for each period between disturbances in CY 2006 are all less than or equal to the threshold friction velocity except for $\mathrm{U}_{1}, \mathrm{U}_{13}, \mathrm{U}_{14}, \mathrm{U}_{25}$ and $\mathrm{U}_{27}$.

The particle size multiplier (k) for $10 \mu$ particles (USEPA 1995 Equation 2) is:

$$
\mathrm{k}=0.5
$$

The emission factor (P) for dry bare soil for $10 \mu$ particles (USEPA 1995 Equation 2) is:

$$
\mathrm{P}=\mathrm{k} \sum \mathrm{P}_{\mathrm{N}}=\text { is } 6.66 \mathrm{~g} / \mathrm{m}^{2}
$$

Thornthwaite's Precipitation Evaporation Index (PE), used as a measure of average soil moisture, is:

$$
\mathrm{PE}=110
$$

The corrected emission factor ( $\mathrm{PM}_{10}$ ) for $10 \mu$ particles (USEPA 1985 Equation 4-1) is:

$$
\mathrm{PM}_{10}=\mathrm{P}(1-\mathrm{V}) /(\mathrm{PE} / 50)^{2}=0.23 \mathrm{~g} / \mathrm{m}^{2} / \mathrm{yr}
$$

The annual wind erosion emission ( E ) is calculated to be:

$$
\mathrm{E}=\mathrm{A}\left(\mathrm{PM}_{10}\right)=179,457 \mathrm{~g} \text { soil }
$$

## ATTACHMENT B

SOURCE TERM DEVELOPMENTAND ANNUAL AIR EMISSIONS

## B. 1 SOURCE TERM DEVELOPMENT

The source term for NFSS NESHAPS calculations was developed considering the radionuclides in the uranium, thorium, and actinium decay series as shown in Table B-1. Concentration data for these radioisotopes were taken from Phases I, II, and III of the Remedial Investigation and are listed in Table B-2. The Phase I sampling was performed from November 1999 through January 2000. The Phase II was performed from August 2000 through October 2000. The Phase III sampling was performed from May 2001 through October 2003. The dataset has been verified to ensure data quality and includes the analysis of soils from biased high locations (i.e., locations that had elevated gamma survey readings). The dataset used for CY 2006 uses higher soil concentrations than in years before CY2004 and more conservatively estimates (biased high) the site concentration values.

The IWCS, completed in 1986 and added to in 1991, is surrounded by sufficient topsoil and compacted clay to consider radionuclide emissions negligible. In 1986, the entire IWCS was covered with 0.9 meters ( 3 feet) of low-permeability, compacted clay, a 0.3 meter ( 12 inch)thick layer of loosely compacted soil, 0.15 meter ( 6 inches) of topsoil and covered with shallowrooted grass. A clay cutoff wall and dike measuring 3.35 to 8.84 meters ( 11 to 29 feet) in thickness formed the perimeter. In 1991 additional soil with residual radioactivity from a vicinity property, along with 60 drums containing radioactive material, were placed over the existing IWCS. Six inches of clay was placed over the waste material and two feet of compacted clay was added on top along with 0.46 meter ( 1.5 feet) of topsoil material. However, the area of the cap was included in the site area estimate.

Radium-226 was detected at an elevated concentration of $1,140 \mathrm{pCi} / \mathrm{g}$ in one area during the Phase I remedial investigation. This was analyzed and determined to come from a stone in the sample. Although release rates are based on dust erosion and not buried stones, this detection was used in the source term calculation.

Soil concentration data, listed in Table B-3, are not available for all the radionuclides in Table B-1. If explicit results for a radionuclide were not available, it was assumed that the radionuclide was present in equilibrium with (i.e., at the same concentration as) the nearest longlived parent. Branching ratios were used to estimate source term concentrations. Table B-3 lists the source term values used in the CAP-88 modeled scenarios.

Table B-1. Radionuclides Considered in NESHAPS Evaluation

| Uranium Series | Thorium Series | Actinium Series |
| :--- | :--- | :--- |
| U-238 | Th-232 | U-235 |
| Th-234 | Ra-228 | Th-231 |
| Pa-234m | Ac-228 | Pa-231 |
| Pa-234 (0.13\%) | Th-228 | Ac-227 |
| U-234 | Ra-224 | Th-227 (98.62\%) |
| Th-230 | *Rn-220 (thoron) | Fr-223 (1.38\%) |
| Ra-226 | Po-216 | Ra-223 |

| Tl-206 (0.00013\%) |  |  |
| *Pb-206 (stable) |  |  |
| P |  |  |

Nuclides with asterisks (*) were excluded from dose calculations for the following reasons: 1) Radon isotopes including thoron and actinon are specifically excluded per the regulation or 2 ) nuclides of low abundance and stable nuclides do not contribute significantly to radiological dose.

Nuclides are presented from top to bottom in order of decay starting from the parent radionuclides. Branching fractions are shown, as appropriate, for consideration in source term development. Fractions taken from Shleien, 1992.

Table B-2. Summary of Phases I, II, and III Characterization Data Used in NESHAP Dose
